# WATERMASTER SERVICE IN NORTHERN CALIFORNIA

1974 SEASON

**JANUARY 1976** 

CLAIRE T. DEDRICK Secretary for Resources The Resources Agency EDMUND G. BROWN JR.

Governor

State of California

RONALD B. ROBIE

Director

Department of Water Resources

#### **FOREWORD**

Bulletin No. 177-74 discusses the watermaster service provided by the Department of Water Resources to areas in Northern California during the 1974 watermaster season. Authority to prepare this report is described in the California Water Code, Division 2, Part 4, Chapter 7.

The bulletin is presented in two parts. The first part contains general information about water rights, water supply, service areas, and watermaster duties. The second part contains sections describing the 18 active service areas, 16 in the Department's Northern District and 2 in the Central District. Each of these 18 sections includes descriptions of the general area, the basis of watermaster service, water supply, method of distribution, 1974 distribution, and other significant information for each area.

Ronald B. Robie, Director Department of Water Resources The Resources Agency State of California

mold b. Mie

#### INTRODUCTION

#### Purpose and Benefits

The primary purpose of watermaster service is to distribute water in accordance with established water rights. This is accomplished by apportioning to the rightful users the available supplies in streams which have had water right determinations.

Distribution of water in watermaster service areas is a continuing statutory function of the Department of Water Resources as provided in Part 5 of Division 2 of the California Water Code.

A major benefit of watermaster service to water users and the State is that court litigation and physical violence, which in past years occurred quite frequently, are essentially eliminated. Under watermaster service each water right owner is assured that his rights are being protected without his having to take legal action against other users. Another important benefit results from increased use of available supplies through reduction of waste.

Because both the water right owners and the State receive benefits from water-master service, the costs of performing the service are shared. The State general tax fund pays half the cost of operating each service area. The water right owners in the service area pay the other half. Individual users' shares are determined in accordance with Article 3 of Chapter 7 of the above-mentioned Part 4 of Division 2 of the Water Code.

#### Determination of Water Rights

Almost all of the streams under state watermaster service have had their water rights defined by the courts under one of three adjudication procedures. These adjudications establish each owner's rights as to allowable rate of diversion, season of use, point of diversion, and place of use. They also establish priorities whereby each owner's rights are ranked in relation to the rights of all other decreed owners. Under this system all rights of any one priority must be fully satisfied before water can be diverted under any lower priority rights. The determinations of the courts are set forth by entering judgments, commonly called decrees.

Water rights determinations necessary for establishing watermaster service areas may be accomplished by "statutory adjudication", "court adjudication", "court reference", permit or license to appropriate, or agreement.

#### Statutory Adjudications

The California Water Code (Sections 2500-2900) prescribes a procedure whereby water users on any stream may petition the State Water Resources Control Board, Division of Water Rights, to make a legal determination of all water rights on that stream. If the Board finds that such a determination is in the best public interest, it proceeds with a statutory adjudication. This adjudication ultimately results in a court decree which defines all water rights on the stream.

#### Court Adjudications

A less extensive method of defining water rights is the "court adjudication" procedure. This type of adjudication results when two or more parties involved in a water rights dispute seek a solution to their problem under civil law. A decision handed down in such a civil action determines only the water rights of the parties involved in the action and

therefore does not necessarily define all water rights on the stream. As a result, serious conflicts sometimes arise between decreed water right owners and persons claiming riparian or appropriative rights which were not specified in the decree.

#### Court Reference

The "court reference" type of adjudication arises when a civil action as

discussed above is referred to the State Water Resources Control Board for a determination under authority contained in Sections 2000-2076 of the Water Code. The Board's report becomes the basis of the court's decision. As in court adjudications, a court reference determines only the water rights of the parties involved in the action.

#### <u>Watermaster Service Areas</u>

#### <u>Formation</u>

Watermaster service is provided in areas where the rights have been defined by the Superior Court of the County, or by agreement, and where an unbiased qualified person is needed to properly apportion the available water according to the established rights. The Director of Water Resources creates watermaster service areas where these conditions exist, following either a request by the users or an order by the Superior Court.

The first watermaster service areas were created in September 1929. Prior to 1929, some watermaster service was provided in accordance with the Water Commission Act of 1913. There are now about 50 streams in Northern California which are under state watermaster service. The two newest service areas were created in 1972.

The counties and principal water sources of the various service areas in Northern California are listed in Table 4. Of

these 20 areas, 18 are in the Department's Northern District, and two in the Central District. In 1974, two service areas in the Northern District, Seiad Creek in Siskiyou County and Pine Creek in Butte and Tehama Counties, were inactive.

#### Description of Region

The service areas are primarily in the mountainous northeastern part of the State where the growing season varies between about 100 and 140 days. Meadow hay and alfalfa are the principal crops under irrigation, although a considerable amount of land is used exclusively for pasturing livestock. Most irrigation is accomplished by gravity systems, with water users diverting directly from the streams at one or more diversion points. However, pumped diversions and sprinkler irrigation systems are becoming popular in some areas.

A map of this region showing the 20 service areas is presented in Figure 1.

#### Watermaster Responsibilities

#### Authority

To assure the proper distribution of water within his service area, each watermaster must ascertain the amount of water available and distribute it both by amount and priority in accordance with established water rights. To

accomplish his responsibility, the water-master is provided authority both by the Water Code and by provisions of pertinent court decrees or voluntary agreements to physically regulate the various streams in the service area. He is further authorized to supervise the design, construction, operation, and maintenance

of diversion dams, headgates, and measuring devices.

Each watermaster supervises water distribution at approximately 100 to 200 diversions in one or more service areas. The need for frequently checking and regulating these diversion points increases substantially in years of short water supply.

#### Control Devices

Permanent measurement and control devices, which the State requires (Water Code Sections 4100-4104) at each owner's main point of diversion, are constructed by the water users under supervision of the watermaster. Installation of accurate, easily set, and lockable structures is a continuing objective of watermaster service, since once they

are built, conflicts among water users almost always stop. Also, the water-master's ability to check and set each diversion regularly is greatly facilitated by good structures.

#### Interpretation of Decrees

The watermaster is often called upon to make immediate field or on-the-spot interpretations of various court decrees, agreements, etc. Since most of these documents were written more than 30 years ago, many situations have developed that were not initially considered. Therefore, the watermaster must use sound, careful, and practical judgment in attempting to reach workable solutions to water disputes. To accomplish this he must possess a good understanding of California water rights law.

#### Water Supply

Water supply in the watermaster service areas is derived principally from unregulated runoff of small streams. Peak runoff, snowmelt in most cases, occurs in the spring, with relatively small streamflow occurring in the summer and early fall. Additional supplies from storage reservoirs and ground water pumping are used in some areas to supplement natural streamflow. However, state watermasters do not supervise the use of ground water in this part of the State.

In some service areas the water supply must be predicted in advance to determine the date watermastering will begin and, to some extent, the manpower needed. The Department's Bulletin 120 series, "Water Conditions in California", is used to assist in these predictions.

#### Precipitation

The streamflow available for distribution is affected by total precipitation, amount of snowpack, air temperature, and the amount of rainfall received during the irrigation season. The latter is

particularly important in the Upper Pit River-Surprise Valley areas, where about 25 to 30 percent of the annual precipitation occurs normally in April, May, and June. Spring storms, which are normally accompanied by relatively cool temperatures, materially affect both the water supply and the demand. Temperatures in the spring affect the demand for water and the manner in which snowmelt runoff occurs. A hot, dry spring depletes the water supply very early, even in years of normal snowpack. A cold, wet spring can extend the supply well into the irrigation season, but cold temperatures retard the growth of crops and are not necessarily desirable.

Data collected at representative snow courses showing the snowpack as of April 1, 1974, on all courses and the snowpack on May 1 and June 1 at selected courses, is presented in Table 1. This information was obtained from the Department's Bulletin 120-74.

Table 2 reports the quantity of precipitation at selected stations in the service areas during the 1973-74 water year.

The seasonal precipitation gives an indication of the related water supply available for distribution and provides a basis for comparing the current year's supply with a long-term average.

#### Streamflow

The general water supply available for diversion within each watermaster area is determined from stream gaging stations placed at key locations in the main stream channels. Several major stations are installed and maintained by the United States Geological Survey

as part of a federal-state program for collection of year-round streamflow records. In addition, several stream gaging stations are installed and operated by the watermasters during the irrigation season to provide supplemental information. Also, water stage recorders are often installed by the watermaster in selected diversion ditches to further assist him in proper distribution of the various water right allotments.

Table 3 presents runoff data at selected stream gaging stations in or near the service areas.

#### SERVICE AREA DESCRIPTIONS AND 1974 NARRATIVES

This portion of the report consists of 18 sections, one for each service area active in 1974, presented in alphabetical order.

Each of these sections begins with a description of the particular service area, including location, geography, and general characteristics. Following this is a section entitled "Basis of Service". Under this heading are presented such data as the case number, date, and type of decrees; a brief summary of the decree or agreement which defines the water rights; the date the service area was created; and other related information.

These sections of the bulletin also present data on the water supply, methods of distribution, significant events of the watermaster season, and daily streamflow records. A map or schematic sketch of the stream system, including diversion locations, roads, etc., is also included for each service area.

A noticeable trend in recent years is the increasing number of water right owners in many areas, due to subdividing or "splitting" of property. For example, in the Ash Creek service area the number increased from 32 in 1967 to 59 in 1972, practically doubling in 5 years. This trend not only causes more work for the individual watermasters,

but makes it difficult to maintain upto-date records of all ownerships and their respective water rights. The water right ownerships are updated as of March 1 each year from County Assessors' records. Changes not on record by March 1 are therefore not reflected on the service area maps included in the various sections.

Since the purpose of this bulletin is to report the activities of the water-master service, and because of the difficulty in keeping the data current, nothing herein should be construed as a determination of water rights. Furthermore, in some service areas there are diversions which may have been active but are not shown on the maps because they did not require the watermaster's attention during 1974.

As in previous years, watermaster service was begun on different dates in the various areas depending upon the streamflow conditions, the ranchers' needs for the water, or; as on some streams, the terms of the decree. Service was continued in all areas through the growing season and was concluded by October 12, 1974.

The date service was started in each service area and the name of the water-master in charge are listed on the following page.

#### Ash Creek Watermaster Service Area

The Ash Creek service area is situated in Modoc and Lassen Counties near the town of Adin, about 100 miles northeast of Redding via Highway 299. Figure 2, page 14, shows the Ash Creek stream system and diversions, plus the roads in the area.

The major sources of water for the service area are Ash Creek and three tributaries, Willow, Rush, and Butte Creeks. Ash Creek rises in Ash Valley in the southeastern part of the service area and flows northwesterly about 18 miles to its confluence with Rush Creek, then southwesterly to the town of Adin, and then westerly to Ash Creek Swamp and the Pit River. Butte and Willow Creek head in the mountains to the east and flow northwesterly into Big Valley. Butte Creek meets Ash Creek near the head of the valley at Adin and Willow Creek about 3 miles farther west near the head of Ash Creek Swamp. The valley floor in this vicinity is at an elevation of approximately 4,200 feet.

#### Basis of Service

The rights on this creek system were determined by a court reference and set forth in Decree No. 3670, Modoc County Superior Court, dated October 27, 1947. From 1949 through 1958 Ash Creek was included as a part of Big Valley watermaster service area. The Ash Creek watermaster service area was created April 3, 1958.

There are 59 water users in the service area with water rights totaling 123.65 cubic feet per second. Approximately 85 percent of the water rights in the service area are in Big Valley, west of the town of Adin. The remaining water rights are along the upstream tributaries and in Ash Valley, east of the town of Adin. The portion of Big Valley served is approximately 10 miles long by 6 miles wide, extending from the

town of Adin to the confluence of Ash Creek and the Pit River.

The Ash Creek decree establishes the number of priority classes on the individual streams within the service area as follows: Ash Creek - five; Willow Creek - four; Rush Creek - one; and Butte Creek - two. Each of these streams is independently regulated.

#### Water Supply

The water supply for Ash and Rush Creeks is derived primarily from snowmelt, since most of the watershed is between 5,000 and 6,000 feet in elevation. Willow Creek and Butte Creek receive a substantial portion of their water from springs. These creeks normally have sufficient water to satisfy demands until about June 1, after which the supply decreases rapidly. By the latter part of June, Ash Creek normally has receded to about 20 cubic feet per second, Willow Creek to about 5 cubic feet per second, and Butte Creek to less than 1 cubic foot per second. The flow of these creeks then remains nearly constant for the remainder of the season.

#### Method of Distribution

Irrigation diversions from Ash Creek and its tributaries are accomplished by small dams placed in the stream channels. Most of the users have several diversion ditches at these dams. These ditches convey the water to the fields where it is spread by means of small laterals. Wild flooding is the predominant method of irrigation, but checks and borders are used to spread the water on some ranches. In a few areas, pumps are used to divert the water into ditches or through sprinkler systems. Return flow is rediverted for use on downstream ranches. In some cases tailwater may be recaptured and recirculated before it returns to the creek.

#### 1974 Distribution

Watermaster service began April 1 and continued until October 12. L. L. Bates, Water Resources Engineering Associate, was the watermaster for this period.

Ash Creek. The available water supply in Ash Creek was sufficient to meet all demands (five priorities) until the first part of May. For most of the remainder of the irrigation season, water was available for first priority allotments only.

The daily mean discharge of Ash Creek at Adin is presented in Table 5, page 12. This stream gaging station is downstream from a substantial number of the diversions; consequently, flows reported do not include all of the available supply of this creek.

Rush Creek. The available water supply in Rush Creek was sufficient to satisfy

all allotments (one priority) until the end of June. By late September the flow had gradually decreased to about 30 percent of these allotments.

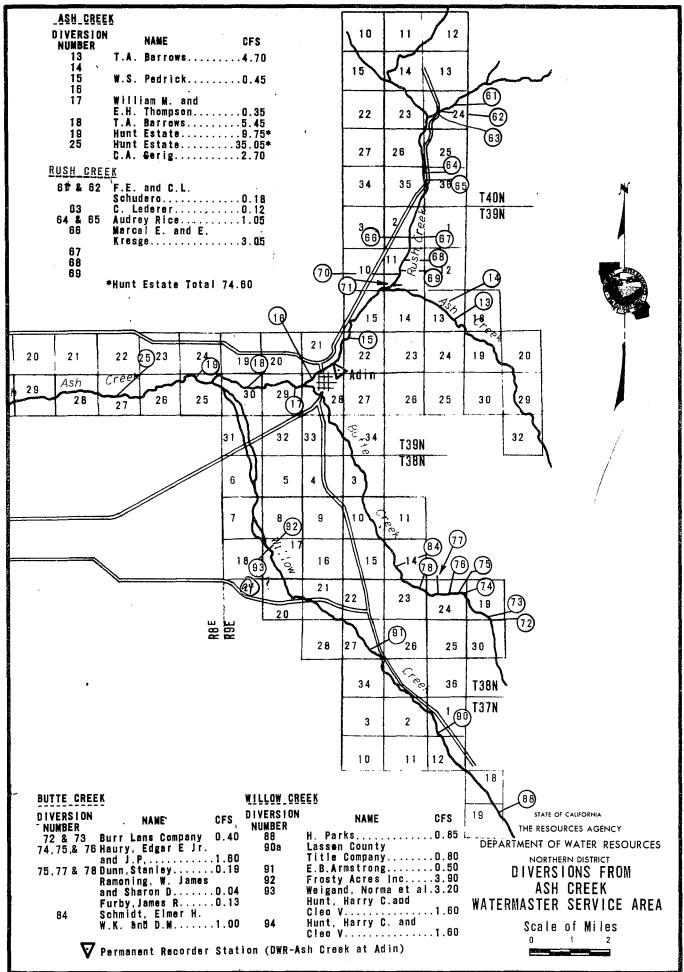

Willow Creek. The available water supply in Willow Creek was sufficient to satisfy all allotments (four priorities) until the first of June. The flow then dropped rapidly, causing regulation of second priority allotments to begin during the first week in June. Throughout the remainder of June and continuing until late August, the flow receded gradually. At this time, and for the remainder of the season, about 50 percent of the second priority allotments were served.

Butte Creek. The available water supply in Butte Creek was sufficient to satisfy all allotments (two priorities) until late spring. During the remainder of the season the flow gradually decreased; however, no distribution problems were encountered.

#### Big Valley Watermaster Service Area

The Big Valley service area is in Modoc and Lassen Counties in the vicinity of the towns of Lookout and Bieber, about 90 miles northeast of Redding via State Route 299.

The Pit River is the major source of water regulated by the watermaster. The river enters the valley north of the town of Lookout and flows southerly through the western part of the valley and out at the southern end. The major area of use is about 13 miles of valley floor, up to 6 miles wide, along the Pit River at an approximate elevation of 4,200 feet.

A map of the Big Valley stream system with towns, roads and diversions is presented as Figure 3, pages 18 and 19.

#### Basis of Service

The Big Valley watermaster service area was created in November 13, 1934, and service began with the 1935 season, operating under an agreement to determine water rights recorded in 1934. The water rights in this service area were set forth in Decree No. 6395, Modoc County Superior Court, a statutory decree, dated February 17, 1959.

Distributing the water on a continuousflow basis, as provided by the decree, has proven impracticable because of the wide variation of flow which frequently occurs. By mutual agreement, an alternative procedure has been established allowing each user a definite amount of water in acre-feet (AF) for each cubic foot per second (cfs) of right allotted by the decree. The watermaster estimates the amount of water available for the next 15 to 30 days and then chooses the appropriate acre-foot/cfs ratio so that the rotation through the valley is completed in not more than 30 days.

There are 58 water users in the service area with total rights of 241.82 cfs,

of which 154.23 cfs are second priority, 29.59 cfs third priority, and 43 cfs fourth priority, with 15 cfs set aside for first priority (stock water and channel storage). Under the decree, the water rights were determined on a basis of 1 cfs per 70 acres of irrigable land.

#### Water Supply

The flow in the Pit River at the head of Big Valley is derived principally from direct runoff, mainly snowmelt, and return flow from irrigation water released from West Valley and Big Sage Reservoirs above South Fork Pit River and Hot Springs Valleys, respectively.

The available water supply in the Pit River as it flows through Big Valley is ordinarily adequate to satisfy all demands until about June 1. The irrigation practices in Hot Springs Valley, about 20 miles upstream from Big Valley, have a significant effect on the available water supply in Big Valley throughout the remainder of the irrigation season. Water users in Hot Springs Valley divert most of the flow of the Pit River for 2- or 3-week periods. Natural flow available for use in Big Valley during these periods is often less than 20 cfs. Periodic releases from channel storage in the lower end of Hot Springs Valley sometimes increase the flow to as much as 200 to 300 cfs for relatively short periods. Consequently, equitable water distribution in Big Valley is very difficult to attain.

Roberts Reservoir, which stores runoff of a minor tributary of the Pit River near the upper end of Big Valley above Lookout, serves as a supplemental source of water to those users in the area who are members of the Big Valley Mutual Water Company. Water from this reservoir is released into the Pit River and distributed to members of the water

company along with the natural flow to which they are entitled.

Iverson Reservoir stores runoff of East Juniper Creek, a tributary to the Pit River at the lower end of Big Valley. This reservoir was completed in 1968 to provide a supplemental water supply for the McArthur and Britten Ranches. Water from Iverson Reservoir is released into the Pit River and then rediverted to the users along with their decreed rights from natural flow of the Pit River.

Records of two stream gaging stations in the Big Valley service area are presented in Tables 6 and 7, page 17.

#### Method of Distribution

Most water users in the Big Valley service area irrigate on a rotation schedule either by wild flooding or by checks and borders. Large flashboard dams placed in the channel make it possible to use the large heads of water characteristic of the supply in the area. In addition, some pumps are used for diversion, both in ditches and directly into sprinkler systems. The ranches which irrigate by wild flooding must use large heads of water in order to cover unleveled or high ground. Much of the runoff is recaptured for use by downstream lands, resulting in a relatively high irrigation efficiency for the valley.

#### 1974 Distribution

Watermaster service began in the Big Valley service area on May 1 and continued through September 30, 1974, with Virgil D. Buechler, Water Resources Technician II, as watermaster.

The season began with Big Sage Reservoir at capacity. West Valley Reservoir started spilling April 23 and continued through June 14. Roberts Reservoir filled during the spring, and Iverson Reservoir almost filled.

The river dams were installed during May at which time a full irrigation

was started. This rotation was completed by June 4.

The flow in the Pit River at Canby was above 500 cubic feet per second from May 1 through May 22 and then gradually decreased to 70 cubic feet per second on June 27, at which time the meadows were dried up for having. During the period June 27 to July 28 the lower users rotated among themselves and irrigated their pasture land. With having operations completed on July 28, the first irrigation after having was started. A rotation using a 5 AF/cfs ratio was started. During this irrigation the Roberts Reservoir shareholders used a supplemental quantity of 786 acre-feet. The Iverson Reservoir shareholders used 30 percent of their storage, or approximately 550 acre-feet. The second rotation, using a 10 AF/cfs ratio, was completed August 27. On this rotation and the next full irrigation, the Roberts Reservoir shareholders used another 562 acre-feet. The Iverson Reservoir users used another 50 percent of their storage, or approximately 700 acre-feet, to receive two full irrigations.

Water delivered from Roberts and Iverson Reservoirs was delivered to the following people:

#### Special Occurrences

Repairs were made to Roberts Reservoir by raising and widening the existing earth dam. Also, a recorder and weir were installed below the outlet to measure the released water.

A headgate and Sparling meter were installed on Herb Hayes' diversion, and a headgate was installed on Dick Bibbens' diversion.

A new 250-horsepower pump (3,000-gpm capacity) was installed with seven sprinkler wheel lines on the Viso (Joiner) Ranch. Sparling meters are to be installed in these systems. Several wheel lines were also installed on the Downey and Duncan Ranches. Meters will be required in these lines to more accurately measure the pumped water.

#### Burney Creek Watermaster Service Area

The Burney Creek service area is in eastern Shasta County above and below the town of Burney. Figure 4, page 23, shows the Burney Creek stream system including the diversions and roads.

The source of water supply for this service area is Burney Creek, which enters the southern part of the service area and flows through Burney in a northerly direction to the Pit River. The portion of the valley served by this stream is approximately 11 miles long and 2 miles wide, and extends both north and south of Burney. The service area is approximately 3,200 feet in elevation.

#### Basis of Service

The rights on this creek system were determined by a court reference and set forth in Decree No. 5111, Shasta County Superior Court, dated January 30, 1926. Watermaster service was provided on the creek from 1926 to 1929 under the old Water Commission Act. The service area was created, along with some others, on September 11, 1929, under a new law passed in that year.

The Burney Creek decree sets forth a rotation schedule of distribution. The water users, however, have found it more beneficial to irrigate on a continuous-flow basis (one priority class plus surplus allotments), which is now normal practice. The water allotted to the Greer-Cornaz Ditch is distributed in accordance with supplemental court decrees.

There are 10 water right owners in the area with total allotments of 33.09 cubic feet per second.

#### Water Supply

The water supply for Burney Creek comes from springs and snowmelt. Most of the watershed lies between the elevations of 4,000 and 7,500 feet on the northeast

slopes of Burney Mountain. The creek normally has sufficient water to supply all demands until about the middle of June. The supply then gradually decreases until the end of July. For the remainder of the irrigation season, runoff from perennial springs keeps the flow nearly constant at approximately 40 percent of allotments.

The daily mean discharge of Burney Creek near Burney is presented in Table 8, page 22. The stream gaging station on Burney Creek is downstream from four points of diversion; consequently, the records do not show all of the available water supply of the creek.

#### Method of Distribution

Water is diverted from Burney Creek, in most cases, by means of low diversion dams, into ditches which convey it to the place of use. Lateral ditches are then used to irrigate the land.

#### 1974 Distribution

The watermaster in the Burney Creek service area was Seth K. Barrett, Water Resources Technician II. Service began June 1 and continued until September 30.

By agreement of the water right owners, all allotments were distributed on a continuous-flow basis.

The water supply for the 1974 season was one of the best on record. This favorable condition, coupled with the fact that the Pierpont Ranch diverted only stockwater and allowed its remaining water rights to be temporarily used by the other diverters, made it unnecessary to apportion the water this season. There was a surplus of flow available to all users most of the time.

#### Special Occurrences

The stream gaging station that normally records the continuous flow was made

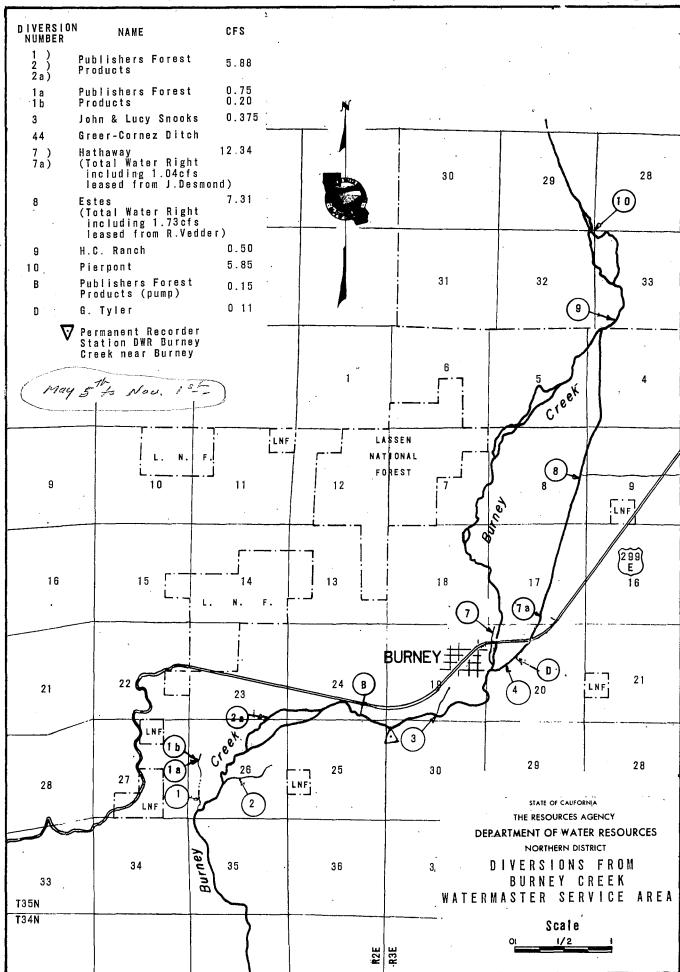

inoperable by early flood conditions. This gage has now been relocated downstream at the Park Street Bridge.

#### Butte Creek Watermaster Service Area

The Butte Creek service area is situated in Butte County a few miles southeast of the City of Chico. The watermaster service area extends for about 11 miles along Butte Creek, commencing approximately 4 miles east of Chico and extending downstream to the crossing of Western Canal. It contains about 20,000 acres of valley floor lands at an average elevation of 150 feet.

A map of the Butte Creek stream system is presented in Figure 5, page 29.

#### Basis of Service

The rights on this stream system were determined by a statutory adjudication and set forth in Decree No. 18917, Butte County Superior Court, dated November 6, 1942. The Butte Creek watermaster service area was created on January 7, 1943.

There are presently 44 water rights owners in the service area (below Diversion 50) with allotments totaling 422.30 cubic feet per second.

The Butte Creek decree established three priority classes for summer use under Schedule 7, a surplus class inferior to the above rights, and a special class for Hamlin Slough. Schedule 3 of the decree defines the rights for rediversion (Diversion 50) of foreign water delivered into Butte Creek from the West Branch of Feather River.

The Water Resources Control Board, on September 18, 1969, granted permits for the following applications to appropriate water from Butte Creek: applications 22321, Gorrill Land Company; 22534, Garrison Patrick; and 22564, Louis C. Camenzind, Jr. These appropriative rights are also under control of the watermaster.

#### Water Supply

Butte Creek, the major source of water, drains approximately 150 square miles of the western slope of the Sierra Nevada Mountains in the northeasterly portion of Butte County above the watermaster service area. The maximum elevation in the watershed is about 7,000 feet.

Normally, snowmelt produces sustained high flows in the creek until about the end of June, after which perennial springs continue to produce flows of more than 40 cubic feet per second. Additional water is imported for distribution from the West Branch Feather River by means of the Hendricks (Toadtown) Canal through De Sabla Reservoir and Powerhouse into Butte Creek.

Records of the daily mean discharge at stream gaging stations in the Butte Creek service area are presented in Tables 9, 10, and 11, pages 26 and 27.

#### Method of Distribution

Water is diverted from Butte Creek by pumping and by gravity diversions. Parrott Investment Company, M & T. Inc., Dayton Mutual Water Company, and Durham Mutual Water Company divert relatively large amounts of water by gravity into ditches leading to their individual distribution systems. Various methods of irrigation are in general practice, including contour checks, strip or border checks, basin checks, furrows, wild flooding, and sprinklers. The use of sprinklers has increased in the past few years, especially for orchards.

#### 1974 Distribution

Watermaster service began April 18, 1974, in the Butte Creek service area and continued until September 30, with Kenneth E. Morgan, Water Resources Engineering Associate, as watermaster.

The available water supply in Butte Creek for the 1974 irrigation season was one of the best on record.

The appropriative water rights of the Newhall Land and Farming Company (application 22039), Gorrill Land Company (application 22321), Garrison Patrick (application 22534), and Louis Camenzind, Jr. (application 22564) were satisfied through their periods of the irrigation season.

The decreed surplus rights of the Newhall Land and Farming Company and the Gorrill Land Company were satisfied throughout the irrigation season.

The lifting of rice allotments by the Federal Government allowed the Gorrill Land Company and the Newhall Land and Farming Company to substantially increase their rice acreage for 1974. The season's crop yields were very good.

# Cow Creek Watermaster Service Area

The Cow Creek service area is in central Shasta County in the foothills east of Redding. Figures 6 through 6e, pages 33 through 38, show the Cow Creek stream system, including the diversions and major access roads.

The source of water supply for this service area consists of three major creek systems. They are North Cow Creek (sometimes referred to as Little Cow Creek), Oak Run Creek, and Clover Creek. These creeks flow in a westerly direction to their confluence in the Millville-Palo Cedro area and thence south to the Sacramento River east of the City of Anderson. The service area is generally a narrow strip of land on both sides of each of these creeks. In some cases water is exported from one creek to the other.

#### Basis of Service

The water rights on each of these creek systems were determined by court references and set forth in separate decrees. Water rights for these creeks were set forth by Shasta County Superior Court decrees as follows:

Creek	Decree No.	Date
North Cow	5804	April 29, 1932
Oak Run	5701	July 22, 1932
Clover	6904	October 4, 1937

The North Cow Creek decree sets forth a rotation schedule of distribution. The water users, however, have found it more beneficial to irrigate on a continuous-flow basis which is now normal practice. Only one priority allotment was provided in each of the Cow Creek service area decrees except for the Oak Run Creek decree which contains a surplus allotment.

The Cow Creek watermaster service area was originally created on October 17,

1932, including North Cow Creek and Oak Run Creek water rights. On January 21, 1938, the service area was expanded to include the Clover Creek rights.

There are 90 water right owners in the area with total allotments of 67.367 cubic feet per second.

### Water Supply

The water supply for this service area is derived mostly from springs and seepage, with some early snowmelt runoff. The watershed varies in elevation from 500 to 5,000 feet and consists primarily of low brushy hills which do not accumulate a heavy snowpack. Relatively large amounts of precipitation during the winter months normally produce substantial seepage and springs that flow through the irrigation season. The creeks normally have sufficient water to supply all demands until late July. The supply then gradually decreases to an average of about 60 to 70 percent of allotments by around mid-September.

The daily mean discharge of North Cow Creek near Ingot is presented in Table 12, page 32. The stream gaging station on North Cow Creek is downstream of many of the diversions and is used by the watermaster primarily to indicate changes in flow conditions rather than amounts of water available. Consequently, the records do not show all of the available water supply of the creek.

#### Method of Distribution

Water is diverted from the creeks, in most cases by means of low diversion dams, into ditches which convey it to the place of use. Lateral ditches are then used to spread it over the land. Irrigation has been on a continuousflow basis instead of by rotation since 1934.

# 1974 Distribution

Seth K. Barrett, Water Resources Technician II, was the watermaster in the Cow Creek service area from June 1 until September 30.

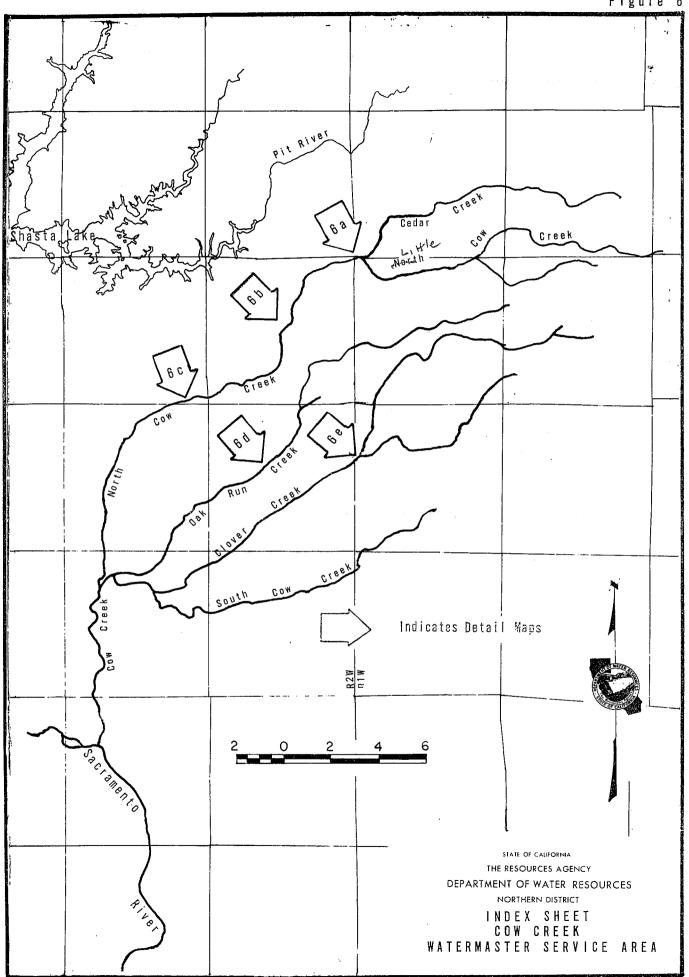

This service area includes Cedar, North Cow, Oak Run, and Clover Creeks. The water supply for the 1974 season was one of the best on record and made it unnecessary to apportion water. In all but Cedar Creek there was a surplus of flow available to all users most of the time.

# Digger Creek Watermaster Service Area

The Digger Creek service area is situated in southeastern Shasta County and northeastern Tehama County.

Digger Creek forms a portion of the boundary line between Shasta and Tehama Counties. It drains an area of approximately 45 square miles on the western slopes of mountains situated immediately west of Lassen National Park. The creek flows in a westerly direction through the town of Manton to its confluence with North Fork Battle Creek. Manton, the only community in the area, is located approximately 40 miles northeast of Red Bluff.

A map of the Digger Creek stream system is presented as Figure 7, page 41.

#### Basis of Service

The rights to use of the waters of Digger Creek were determined by five court adjudications. The Crooker Ditch, now combined with the Harrison Ditch, may divert all the water in the creek at its point of diversion. Diversions below this point, though defined by decree, are not in the service area.

Four Tehama County Superior Court decrees define the rights included in the service area. These decrees are listed on page 40.

The four decrees have, in effect, divided the water rights on the creek into two groups, the upper users and the lower users. The three upper users irrigate land adjoining the stream so that all water not consumptively used returns to Digger Creek. The lower users are located within a 5-squaremile area. Very little runoff from the lower users returns to the creek.

The water rights of the three upper users are absolute and not correlative to the lower users; therefore, allotments are

not cut proportionally as Digger Creek flows decrease. Since the lower users have to stand all deficiencies, the upper users, in effect, have first priority allotments, and the lower users have second and third priority allotments.

The Digger Creek watermaster service area was created June 11, 1964, and watermaster service has been provided each year since that time. There are 38 water right owners in the area with total allotments of 23.225 cubic feet per second.

## Water Supply

Precipitation, occurring principally in the winter months, is typical of Northern California foothill areas. Snowmelt contributes to the early runoff but the summer streamflow is primarily from springs. In average runoff years there is sufficient flow in Digger Creek, with careful regulation, to satisfy all decreed allotments throughout the entire irrigation season. However, serious deficiencies occur in dry years.

The estimated daily mean discharge of Digger Creek below the mouth of the South Fork is presented in Table 13, page 40.

#### Method of Distribution

Irrigation is accomplished principally by wild flooding, although border checks and sprinklers are used on a few fields. Small diversion dams are placed in the stream channel to divert water into ditches for conveyance to the fields.

#### 1974 Distribution

Watermaster service began in the Digger Creek service area on June 1 and continued through September 30. Seth K. Barrett, Water Resources Technician II, was the watermaster during this period.

The water supply for the 1974 season was one of the best on record. There was a at all times; therefore, apportionment of the water was unnecessary. surplus flow past the lowest diversion

# French Creek Watermaster Service Area

The French Creek service area is situated in Scott Valley, western Siskiyou County, near the town of Etna. The major sources of water supply are French, Miners, and North Fork French Creeks. French Creek flows in a northeasterly direction through the central part of the service area. Miners Creek begins east of the headwaters of French Creek and flows in a northerly direction, joining French Creek about 3 miles above its confluence with Scott River. North Fork French Creek begins north of the headwaters of French Creek and flows easterly, joining French Creek 1 mile upstream from the confluence with Miners Creek.

The service area encompasses the entire agricultural area within the French Creek Basin, and some additional lands along the west side of the Scott River near the town of Etna. The service area is about 1/2 mile wide and 5 miles long, with the main axis and drainage running from south to north. Elevations of the agricultural area range from about 3,200 feet at the south to about 2,800 feet at the confluence of French Creek and Scott River.

A map of the French Creek stream system with the diversions and roads is presented as Figure 8, page 45.

#### Basis of Service

The rights on this creek system were determined by a court reference and set forth in Decree No. 14478, Siskiyou County Superior Court, dated July 1, 1958.

Water is distributed according to three schedules: North Fork French Creek with three priorities; Miners Creek with three; and the French Creek, Horse Range Creek, Paynes Lake Creek, and Duck Lake Creek system with seven.

These schedules are independent of each other with two exceptions. These involve the use of some Miners Creek users having the option to divert from French Creek when water is not available from Miners Creek. These rights are further limited by specifying maximum allowable flows at given points, regardless of the source of the water.

One peculiarity of this decree is that it included two water rights that have a specified amount but are subject to the exclusive control of the other owners of the ditch.

The French Creek watermaster service area was created on November 19, 1968, and service was started on July 1, 1969.

There are 27 water users in the service area with water rights totaling 30.59 cubic feet per second.

# Water Supply

The water supply is derived from snowmelt runoff, springs and seepage, and occasional summer thundershowers.

The watershed of French Creek contains about 32 square miles of heavily forested, steep, mountainous terrain of the easterly slopes of the Salmon Mountains. It varies in elevation from about 7,200 feet along its west rim to about 3,200 feet at the foot of the slopes bordering French Creek Valley. Snowmelt runoff is normally sufficient to supply all demands until about the middle of July. The daily mean discharge of Duck Lake Creek, a tributary, is presented in Table 14, page 44.

# Method of Distribution

Irrigation is accomplished primarily by wild flooding, with permanent pasture and alfalfa fields comprising the major

crops. Water is conveyed by ditches and laterals to the place of use.

#### 1974 Distribution

Watermaster John A. Nolan, Water Resources Technician II, was on duty in the French Creek service area from July 1 until September 30.

Because watermaster service was initiated during the 1969 season, few data are available for a water supply comparison with past years. However, it is the opinion of most ranchers in the area that water-year conditions were definitely above average.

Upper third priority allotments were shut off on August 25 to satisfy the upper second priority rights. However, some third priority allotments lower downstream were available throughout the remainder of the season.

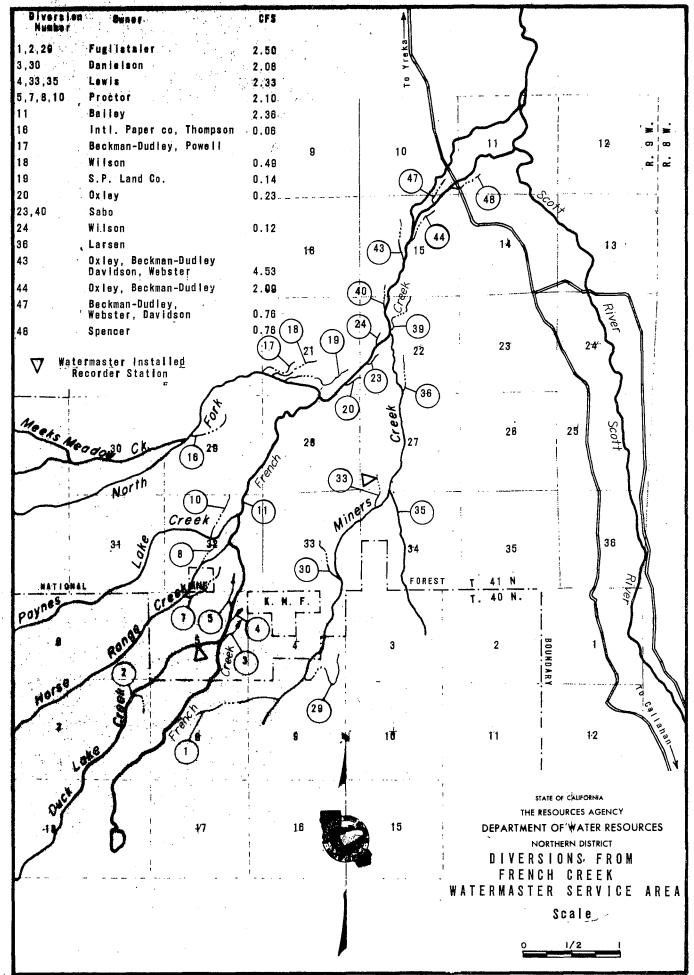

Those with downstream first, second, and third priority allotments can rely on a more dependable water supply than the upper users due to inflow from Paynes Lake, Horse Range, and North Fork French Creeks, all tributaries to French Creek below the upper users.

# Hat Creek Watermaster Service Area

The Hat Creek service area is in the eastern part of Shasta County north of Lassen Volcanic National Park. The maps, Figures 9 through 9b, pages 49 through 51, show the Hat Creek service area and stream system, including locations of the diversions of the upper and lower user groups.

Hat Creek, which flows in a northerly direction through the area, is the only source of water supply in the service area. The place of use is Hat Creek Valley, which is approximately 20 miles long and 2 miles wide, extending northward from about 3 miles south of the town of Old Station to the confluence with Rising River. The irrigable lands, which consist primarily of volcanic ash, are interlaced with large outcroppings of volcanic rocks.

#### Basis of Service

Water from Hat Creek is distributed under provisions of court reference adjudications which resulted in Decree No. 5724, dated May 14, 1924, and Decree No. 7858, dated May 7, 1935, Shasta County Superior Court. Decree No. 5724 established irrigation and nonirrigation allotments for 18 periods of rotation between "upper" and "lower" user groups for the period of May 1 to October 28 annually. Decree No. 7858 established 3 allotments for continuous irrigation, May 1 through October 28, and allotments for the period October 28 to May 1 annually for all users. These latter rights are not normally supervised by the watermaster.

Watermaster service in the Hat Creek area has been provided in accordance with the decree since 1924. The existing service area was created on September 11, 1929.

Decree No. 5724 defines the allotments in two separate schedules: upper and

lower users, requiring 10-day rotations beginning at 6 a.m., May 1, and terminating at 6 a.m., October 28. All water rights are of the same priority, with the surplus flows distributed according to the users that are on rotation. The upper users' water rights require 154.7 cubic feet per second and lower users require 166.5 cubic feet per second. The lower users require more because of additional channel loss. When the upper users are being served, the lower users receive a minimum flow for stock water.

### Water Supply

The water supply of Hat Creek is derived from snowmelt runoff from Lassen Peak and from large springs. Snowmelt normally creates a high flow during May and June, but the substantial portion of the summer supply comes from large springs which decrease only slightly in output. Only after a series of dry years does the flow of these springs fall much below 75 percent of total allotments.

A record of the daily mean discharge of Hat Creek near the town of Hat Creek is presented in Table 15, page 48.

# Method of Distribution

Most irrigation in the area is accomplished by wild flooding. Large heads of water are used to cover the land rapidly, thereby preventing excessive loss from percolation in the extremely porous soil. Diversion dams constructed across the creek serve to divert water into large ditches. The fields, many of which have checks and borders, are then flooded from the main diversion ditches or from laterals. A few domestic rights are met by pumping directly from Hat Creek.

### 1974 Distribution

Virgil Buechler, Water Resources Technician II, served as watermaster in the Hat Creek service area from May 1 until September 30.

The 1974 irrigation season was very successful due to an above-normal snow-pack on Lassen Peak. The flows remained above the 165 cfs water right for the

entire season and peaked in excess of 400 cfs in June. Only one 10-day rotation schedule was required for the lower users. This rotation was initiated September 8. As the season ended, the demand slacked off and the flows picked up as the weather cooled.

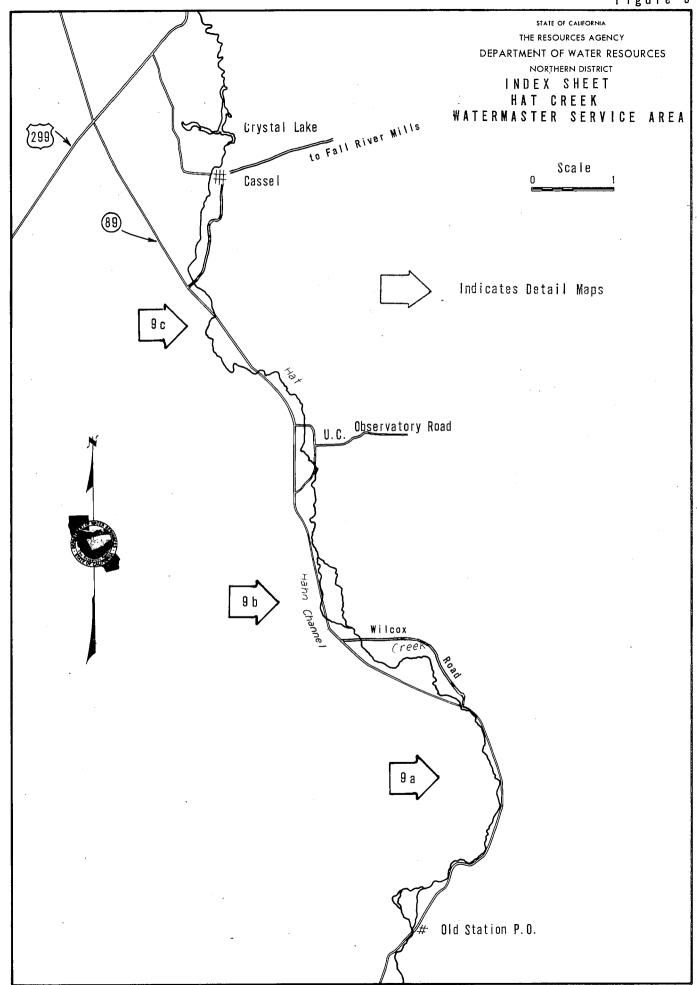

#### Special Occurrences

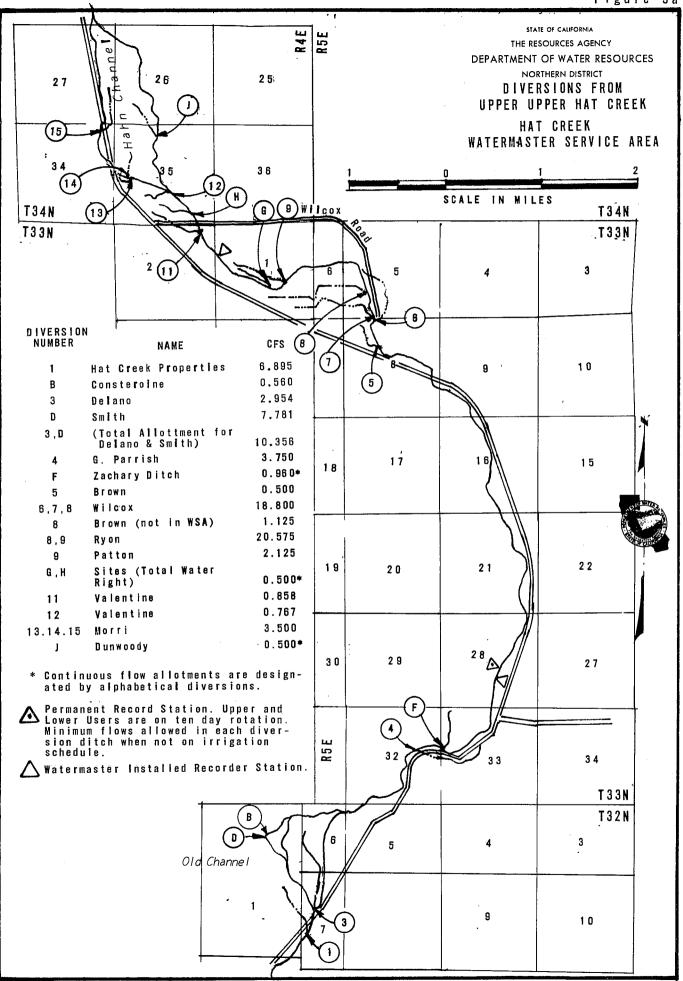

A metal screw-type headgate was installed on the Lonquist Diversion.

# Indian Creek Watermaster Service Area

The Indian Creek service area is located in the north central part of Plumas County in the vicinity of the town of Greenville.

The major sources of supply in the service area are Indian Creek and two major tributaries, Wolf Creek and Lights Creek. Indian Creek and its minor tributaries rise in the mountains east of the service area. It then flows through Genesee Valley and through Indian Valley past the towns of Taylorsville and Crescent Mills to its confluence with the North Fork Feather River. Indian Creek is joined on the north by Lights Creek in the southeast part of Indian Valley and by Wolf Creek in the northwest part of the valley. The major place of use is in Indian Valley, an irregular-shaped area of about 20 square miles. The average elevation is about 3,500 feet.

Maps of the whole area and of each major stream system within the Indian Creek service area are presented as Figures 10 through 10c, pages 55 through 58.

#### Basis of Service

The Indian Creek watermaster service area was created on Feburary 19, 1951, to include, with certain exceptions, the water rights set forth in Decree No. 4185, entered December 19, 1950, by the Superior Court of Plumas County, and the rights under Permit 7665 issued in approval of Application 12642 subsequent to entry of the decree. The statutory proceeding leading to the decree was entitled "In the Matter of the Determination of the Rights of the Various Claimants to the Water of Indian Creek Stream System in Plumas County, California".

The service area has been amended twice. Watermaster service has been provided during each irrigation season since the service area was created, and annual reports have been prepared to show the work accomplished.

There are currently 45 water right owners in the service area with total allotments amounting to 97.015 cubic feet per second.

The Indian Creek decree establishes three priority classes for each of the major stream systems within the service area.

### Water Supply

The water supply in the Indian Creek service area is derived primarily from snowmelt runoff with springs and seepage maintaining some late summer flows. The flow of Wolf Creek is normally sufficient to supply all allotments until June 1. Indian and Lights Creeks, with the exception of some tributaries, have sufficient flow to supply all allotments until July 1. After these dates, the flow steadily decreases throughout the season until by the end of August only a small portion of allotments is available.

A record of the daily mean discharge of Indian Creek near Taylorsville, where Indian Creek enters the valley, is presented in Table 16, page 54.

# Method of Distribution

The basic method of irrigation in Indian Valley is wild flooding. Small diversion dams are constructed in the stream channels to divert water into distribution ditches for conveyance to the fields. Small check dams, located throughout the fields in swales, help to spread the water over the ground. There is a limited amount of check and border irrigation in the valley. A few sprinkler systems are also in use.

#### 1974 Distribution

Watermaster service began in the Indian Creek service area on April 8 and continued until September 30 with Harvey M. Jorgensen, Water Resources Engineering Associate, as watermaster.

The available supply in the service area was above average during the season.

Wolf Creek. The available water supply of Wolf Creek was sufficient to satisfy all allotments (three priorities) until August 15. The streamflow gradually decreased until only first priority allotments were being served on September 1.

Lights Creek and Tributaries. The available water supply of Lights Creek was sufficient to satisfy all allotments (three priorities) until August 20, when the surface flow at the county road stopped. The available water supply of Cooks Creek satisfied all allotments until July 30.

Indian Creek. The available water supply of Indian Creek was sufficient to satisfy all allotments (three priorities) until August 5. Sufficient underflow occurred below the Mill Race Diversion Dam to meet allotments of downstream users.

### Special Occurrences

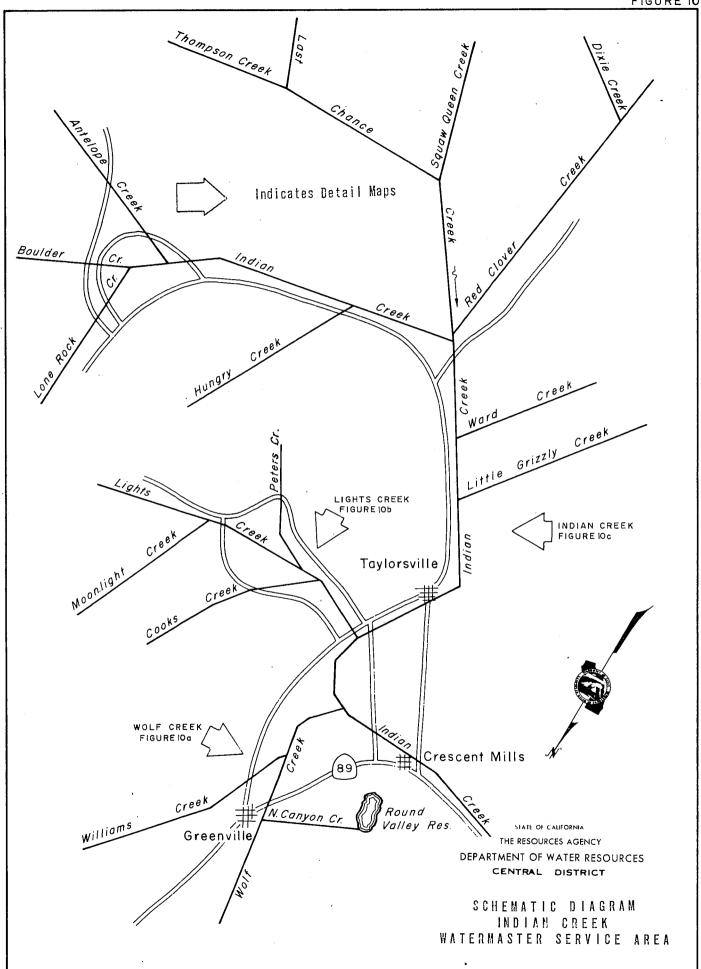

Orifice plate control devices were installed in Diversion 54 to facilitate the release of water from Antelope Lake past these diversion points.

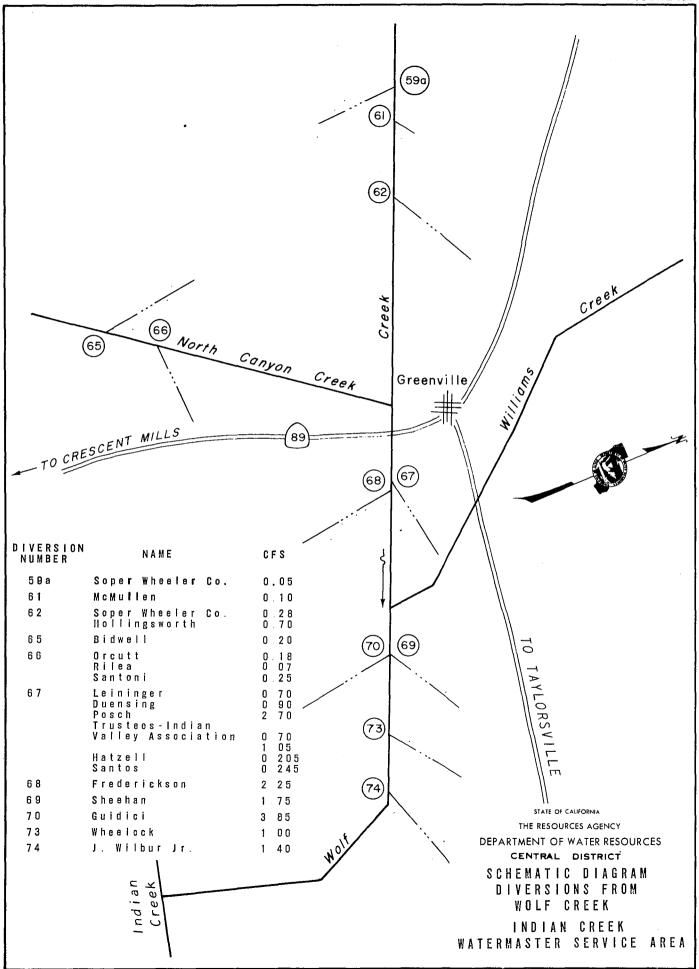

Diversion 70 on Wolf Creek was relocated 1,000 feet upstream.

# Middle Fork Feather River Watermaster Service Area

The Middle Fork Feather River service area is located in and around Sierra Valley, a plateau area on the west slope of the Sierra Nevada Mountains in the eastern portion of Sierra and Plumas Counties.

Major sources of supply for this service area are the Middle Fork Feather River and its tributaries in the Sierra Valley. The area is comprised of five major stream groups. These groups, starting in the northeast corner of the valley and proceeding in a clockwise direction, are Little Last Chance Creek, Smithneck Creek, Webber Creek and tributaries, West Side Canal, and Fletcher Creek and Spring Channels. The Middle Fork Feather River flows generally north for approximately 15 miles through Sierra Valley. It then flows out of the valley in a westerly direction near Beckwourth. The major place of use is in Sierra Valley, which is about 15 miles long and 10 miles wide. The average elevation of the valley floor is 4,900 feet.

Maps of the Middle Fork Feather River service area are presented as Figures 11 through 11K, pages 62 through 73.

#### Basis of Service

The Middle Fork Feather River water-master service area was created on March 29, 1940, to include, with the exception of certain tributaries and springs, all water rights set forth in Decree No. 3095 entered in the Middle Fork Feather River statutory adjudication proceeding on January 19, 1940, Superior Court, Plumas County.

The decree establishes the number of priority classes for each of the major stream systems within the Middle Fork Feather River service area as follows: Little Last Chance Creek - eight; Smithneck Creek - five; West Side Canal Group - five; Fletcher Creek and Spring

Channels - three; Webber Creek and tributaries - six; and Sierra Valley Water Company - one.

The service area has been amended three times to include and exclude certain water rights. Watermaster service has been provided during each irrigation season since the service area was created and annual reports have been prepared to show the work accomplished.

There are, currently, 100 water right owners in the service area with total allotments amounting to 371.565 cubic feet per second.

### Water Supply

The major water supply in the Middle Fork Feather River service area is derived from snowmelt runoff, with minor flow from springs and from supplemental stored and foreign water.

Natural flows of Little Last Chance Creek are supplemented by reservoir storage provided by Frenchman Dam which was constructed by the Department of Water Resources in 1961. Stored water is released and used as needed under the provisions of an annual contract.

Smithneck Creek flow is normally sufficient to supply all allotments until about the middle of May. It then decreases until about June 1 and only first and second priority allotments are then available for the remainder of the season.

The natural flow of Webber Creek is normally sufficient to supply all allotments until the middle of May. At that time up to 60 cubic feet per second is diverted from the Little Truckee River to supplement the flow. This imported water is diverted through the Little Truckee Ditch into Onion Creek and then

into Webber Creek, via Cold Stream, for use of shareholders in the Sierra Valley Water Company. This supplemental supply decreases rapidly during July, producing only a small quantity during the latter part of the season.

The West Side Canal streams normally supply all allotments until the first part of June. The flow then gradually declines throughout the season.

The flow of Fletcher Creek and Spring Channels normally supplies all allotments until July 1. The flow then gradually declines for the remainder of the season.

Records of the daily mean discharge of Little Truckee Ditch and the Middle Fork Feather River near Portola are presented in Tables 17 and 18, page 61.

#### Method of Distribution

Wild flooding is employed by the majority of the water users to irrigate their fields. Small diversion dams are placed in the stream channels to divert the water into individual distribution systems. Check dams are constructed in the swales to implement flooding once the water reaches the fields.

#### 1974 Distribution

Watermaster service began April 1 in the Middle Fork Feather River service area and continued until September 30. Joe Nessler, Water Resources Engineering Associate, was Supervising Watermaster during this period. Conrad Lahr, Water Resources Technician II, assisted as Deputy Watermaster. The available supply in the service area was about average during the season.

Little Last Chance Creek. Frenchman Dam and Reservoir began its thirteenth season of operation. An annual contract concerning storage, distribution, and sale of water was again negotiated with the Last Chance Creek Water District. Delivery and distribution of water was made in accordance with the provisions of the contract and the instructions of the District's Board of Directors.

Smithneck Creek. The available water supply was sufficient to satisfy all allotments (five priorities) until about May 20. A 2-week rotation schedule was started May 18 and continued for 8 weeks until only stockwater was available.

Webber Creek and Tributaries. The natural flow of Webber Creek was sufficient to supply all allotments (six priorities) until about the first of June. It then decreased gradually until first and second priority allotments were being served at the end of the season. Importation of water from the Little Truckee River began on May 30, supplementing the natural flow of Webber Creek to help satisfy all allotments of the Sierra Valley Water Company shareholders (one priority). A total of 2,960 acre-feet of water was diverted through the Little Truckee Ditch up to September 30. This diversion provided sufficient water until about August 10. A lighter-than-normal demand still exists in this stream system due to damaged diversion facilities.

West Side Canal Group. The available water supply in the West Side Canal Group, consisting of Hamlin, Miller, and Turner Creeks, was sufficient to satisfy all allotments (five priorities) until the middle of July.

Fletcher Creek and Spring Channels. Ample water was available to satisfy all allotments until July 1. A rotation schedule was set up on Fletcher Creek and continued for the remainder of the season.

SCHEMATIC DIAGRAM FLETCHER CREEK AND SPRING CHANNELS

# North Fork Cottonwood Creek Service Area

The North Fork Cottonwood Creek service area is situated in Shasta County near the town of Ono west of Redding. Figure 12, page 77, shows the North Fork Cottonwood Creek stream system including the diversions and roads.

The source of water supply for this service area is the North Fork of Cottonwood Creek and its two major tributaries, Moon Creek and Jerusalem Creek. The North Fork of Cottonwood Creek flows through the service area in a southeasterly direction to its confluence with the other two major forks of Cottonwood Creek and then to the Sacramento River east of the town of Cottonwood. The service area consists of sparsely scattered parcels separated by steep, brushy hills. These lands are at about the 1,000-foot elevation.

### Basis of Service

The water rights on this creek system were determined by court reference and set forth in Decree No. 5479, Shasta County Superior Court, dated June 9, 1920. The North Fork Cottonwood Creek watermaster service area was created September 11, 1929; however, service was provided intermittently in accordance with the decree since 1924. There are 13 water right owners in the area with total allotments of 30.30 cubic feet per second, all with equal priority.

#### Water Supply

Snowmelt contributes to the flow in the North Fork Cottonwood Creek system during the early part of the irrigation

season. However, perennial springs provide the major source of supply during the summer and fall months. The flow is normally sufficient to supply all demands. In dry years, however, the available supply may be as low as 30 to 40 percent of the decreed allotments.

A record of the daily mean discharge of North Fork Cottonwood Creek near Igo is presented in Table 19, page 76. This gaging station is downstream from most diversion points on the creek, but gives a general indication of the water supply.

### Method of Distribution

The general practice throughout the area is to irrigate by wild flooding. One water user, however, pumps directly from the creek using a sprinkler system to irrigate his crops. Pumping was necessary at this diversion point because the irrigated land was considerably higher in elevation than the creek channel.

### 1974 Distribution

Seth Barrett, Water Resources Technician II, was the watermaster for the North Fork Cottonwood Creek service area beginning June 1 and continuing until September 30.

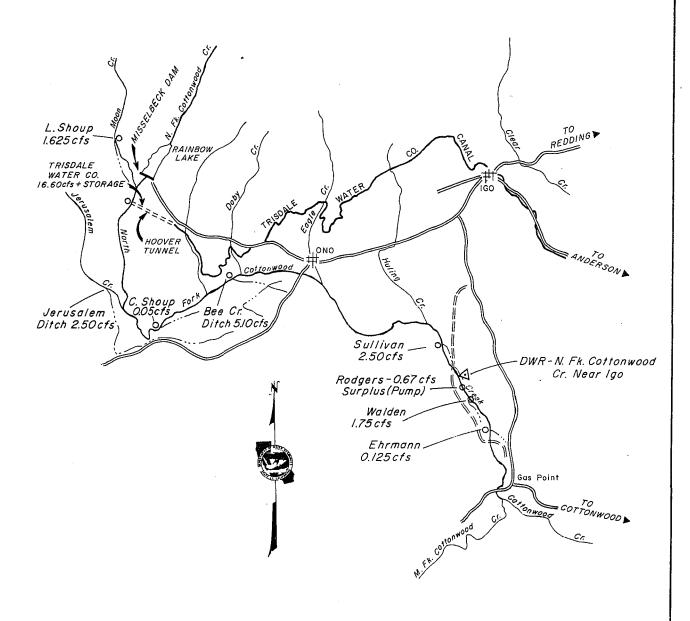

The water supply for the 1974 season was one of the best on record. There was a surplus of flow past the lowest diverter at all times during the season; therefore, apportionment of the water was unnecessary.

DIVERSIONS FROM
NORTH FORK COTTONWOOD CREEK
WATERMASTER SERVICE AREA

# North Fork Pit River Watermaster Service Area

The North Fork Pit River service area lies along the west slopes of the Warner Mountains in northeastern Modoc County and extends southward from the Oregon border about 45 miles to just south of Alturas.

Eight small independent streams draining the west slope of the Warner Mountains and generally following a westerly direction comprise the major source of water supply. Three of these streams, New Pine, Cottonwood, and Davis Creeks, are tributary to Goose Lake. The other 5 are tributary to the North Fork Pit River. From north to south these are: Linville, Franklin, Joseph, Thoms, and Parker Creeks.

The North Fork Pit River flows in a southerly direction from the south rim of Goose Lake Basin to its confluence with the South Fork Pit River immediately below Alturas. The basins of Goose Lake and the North Fork Pit River may be considered as completely separate, since the lake has not spilled into the river for nearly 100 years.

The place of use in the northern half of the area lies in a relatively long, narrow, sloping strip extending between the east shore of Goose Lake and the foothills of the Warner Mountains. The places of use in the southern half of the area, which are supplied from the North Fork Pit River and its tributaries, are primarily in the narrow valleys bordering the streams. The elevation of the places of use range from about 4,350 feet just below Alturas to about 5,200 feet at the upper portions on some of the creeks.

Maps of the North Fork Pit River watermaster service area and of the separate stream systems within the area are presented as Figures 13 through 13j, pages 88 through 98.

### Basis of Service

There are 91 water right owners in the service area with allotments totaling 214.55 cubic feet per second. Table 20, page 80, briefly outlines the five decrees covering the area and presents data relative to establishment of watermaster service and water rights.

### Water Supply

The water supply is derived primarily from snowmelt for all streams in the North Fork Pit River service area except Linville Creek, which, having a relatively small drainage area, is almost entirely spring fed. After mid-June, the rest of the streams also depend on springs, but diminish rapidly until mid-July, after which the flow remains fairly constant. There are several small reservoirs in the area, but they are used essentially as regulatory storage.

# Method of Distribution

Distribution is accomplished by diversion structures in the main channels diverting into ditches which convey the water to its place of use. Wild flooding from small feeder ditches is the common method of application. There is, however, increasing use of sprinkler systems, some directly from ditches with supplemental ground water being added as the surface flow diminishes. Subirrigation by the use of large flashboard dams to raise the water level in the channel is practiced along the North Fork Pit River between Parker Creek and Alturas.

### 1974 Distribution

Watermaster service in the North Fork Pit River service area was begun on April 7 and continued through September 30. Eldon E. Rinehart, Water Resources Engineering Associate, was the watermaster for all the streams in the area

except Parker and Shields Creeks, which were handled by L. L. Bates, Water Resources Engineering Associate.

New Pine Creek. Surplus water was available to New Pine Creek water right owners through June 30, the period that the proration or correlative system of distribution was in effect. Beginning July 1, distribution is based on the priority system in accordance with the decree. Fourth priority allotments were satisfied until July 12. Following that date, the flow gradually decreased to 5.5 cfs, or enough to satisfy the first, second, and approximately 95 percent of the third priority allotments at the end of the watermaster season on September 30.

Cottonwood Creek. The flow in Cottonwood Creek was adequate to satisfy all six priorities until May 11. Thereafter the flow dropped rapidly to May 15 when only sufficient water was available to meet about 47 percent of first priority allotments. The flow remained fairly constant through July, but then dropped off until at the end of the season on September 30 only enough flow remained to supply about 11 percent of first priorities.

Davis Creek. The water supply in Davis Creek was sufficient to satisfy all allotments until June 7. Thereafter the flow gradually diminished. Third priority allotments were met until June 16, and second priority allotments were served throughout the remainder of the season. On September 30 the flow was 6.4 cfs, or sufficient to meet first, second, and about 4 percent of the third priority allotments.

Linville Creek. Spring-fed Linville Creek maintains a remarkably uniform flow throughout the watermaster season. The available water supply in the creek remained fairly constant from the start of the 1974 season when the flow was about 3.0 cfs to the end of the season when the flow was 2.5 cfs. The flow was sufficient to meet 100

percent of first priority allotments and 2 percent of second priority allotments.

Franklin Creek. The water supply in Franklin Creek was sufficient to satisfy all allotments from April 23 through June 2. All third priority rights were met until June 7; the flow then gradually decreased to 4 cfs on June 29, at which time all of the first, second, and about 22 percent of the third priority allotments were being met. From then until mid-September the flow remained fairly uniform. On September 15 when the winter schedule of priorities became effective, the flow was 3.4 cfs, or enough to satisfy the first and second priority rights of the winter schedule.

Joseph Creek: A surplus water supply existed in Joseph Creek from the beginning of the watermaster service until June 12. The flow then gradually decreased to July 15 when it measured 3.3 cfs, or sufficient to satisfy the first priority rights and about 33 percent of second priority rights. The flow remained fairly constant until mid-August, then gradually diminished to 2.5 cfs on September 30 when the watermaster season ended. Thus, the first priority rights were met throughout the season.

Thoms Creek. The water supply in Thoms Creek was adequate to supply all allotments until June 13. Thereafter the flow decreased fairly uniformly to the end of the watermaster season on September 30, when the flow was 0.1 cfs, or sufficient to meet 10 percent of the first priority allotments.

North Fork Pit River. A surplus water supply existed in the North Fork Pit River until May 22. Following that date the flow gradually decreased until July 15, when only the first priority allotments were being met. The flow gradually declined until September 30 when the flow was 5.8 cfs, or enough to meet approximately 75 percent of first priority allotments.

Parker Creek. The flow was sufficient to satisfy all four priorities until June 7. A portion of fourth priorities was served until June 14. All first and second priorities received full allotments, but thirds decreased from 71 percent to 6 percent for the remainder of the season.

Shields Creek. There was sufficient flow to serve all four priorities until July 18. First, second, and third priorities were then served until August 5, at which time the flow had receded until only first and approximately 60 percent of seconds were satisfied for the rest of the season.

# Shackleford Creek Watermaster Service Area

The Shackleford Creek service area is located in western Siskiyou County near the town of Fort Jones in Scott Valley. The major sources of water supply for this service area are Shackleford Creek, which flows through the central part of Quartz Valley, and its tributary, Mill Creek, which rises east of the headwaters of Shackleford Creek. Evans Creek, a small tributary to Mill Creek, enters from the south.

The service area encompasses the Quartz Valley region of Scott Valley and includes the entire agricultural area within the Shackleford Creek Basin. It is about 2 miles wide by 6 miles long with the main axis and drainage running from south to north. Elevations on the agricultural area range from about 3,100 feet at the south to about 2,650 feet at the confluence of Shackleford Creek and Scott River.

A map of the Shackleford Creek stream system is presented as Figure 14, page 101.

# Basis of Service

The Shackleford Creek watermaster service area was created on November 6, 1950. Water is distributed under the provisions of a statutory adjudication which resulted in Decree No. 13775, Siskiyou County Superior Court, dated April 3, 1950.

The allotments are defined in four separate schedules. The Upper Shackleford Creek Group and Lower Shackleford Creek Group each have seven priority classes and the Upper Mill Creek Group and Lower Mill Creek Group each have three priority classes.

Along with these schedules of allotments during the irrigation season, the decree defines two storage rights upstream of all other diversions. This stored water is released late in the irrigation season and commingled with the natural flow of Shackleford Creek for use by the owners.

There are presently 42 water users in the service area with allotments totaling 64.73 cfs.

### Water Supply

The water supply for Shackleford Creek is derived from snowmelt runoff, springs and seepage, and supplemental stored water released from Cliff Lake and Campbell Lake. These lakes are located near the headwaters of Shackleford Creek.

The watershed of the Shackleford Creek stream system contains about 31 square miles, located in the heavily forested, steep, mountainous terrain of the northeasterly slopes of the Salmon Mountains. It varies in elevation from about 7,000 feet along its west rim to about 3,000 feet at the foot of the slopes bordering Quartz Valley. Snowmelt runoff is normally sufficient to supply all demands until the middle of July. The supply then usually decreases until the first part of August when water is released from Cliff and Campbell Lakes to maintain sufficient flow for second priority allotments in the Shackleford Ditch.

### Method of Distribution

Irrigation is accomplished primarily by wild flooding of permanent pasture and alfalfa fields. Water is distributed by ditches and laterals to the places of use. Shackleford Ditch, the largest of these ditches, has a length of about 6 miles and a capacity of about 12 cubic feet per second.

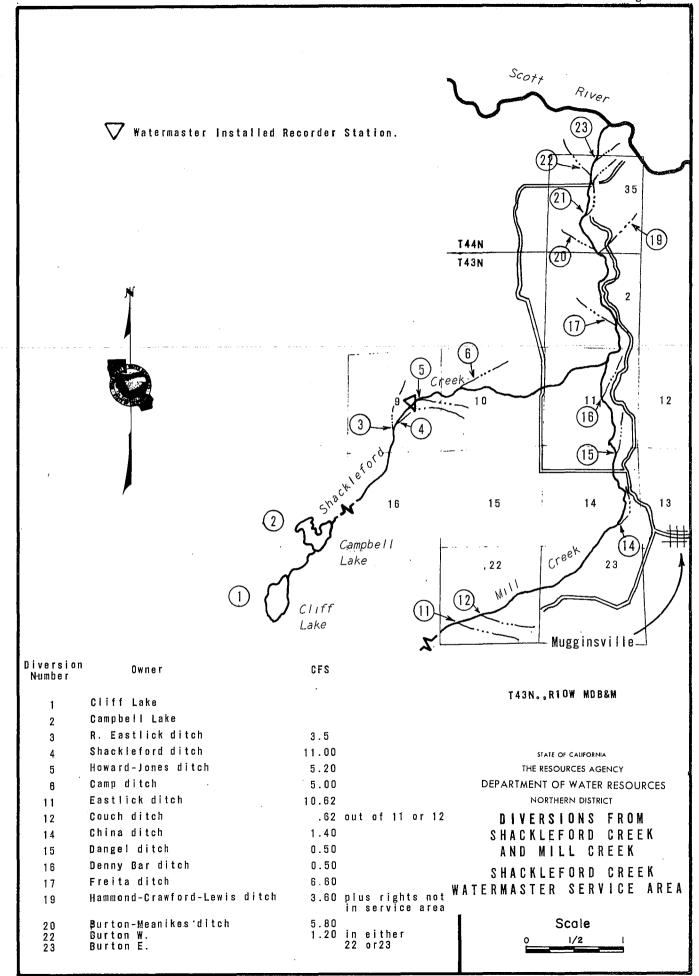

### 1974 Distribution

Watermaster service began June 1 in the Shackleford Creek service area and

continued until September 30, with John A. Nolan, Water Resources Technician II, as watermaster.

The available water supply was excellent throughout the entire season. The Shackleford Ditch (Diversion 4) suffered considerable damage from the severe storms in January 1974 and was not repaired until late September. As a result, the large second priority water right allotment for this ditch

was available for lower priority water right owners. Another factor for the excellent late season water supply was that the Department of Water Resources' Division of Safety of Dams required that the dam at Campbell Lake (Diversion 2) be improved. The owners of this storage right had to drain the lake to make the necessary repairs, thus making this water available for lower priority water right owners.

# Shasta River Watermaster Service Area

The Shasta River service area is situated in the central part of Siskiyou County, south and east of the town of Yreka.

The source of water supply is Shasta River and its several tributaries. upper reaches of the service area are served by two groups of tributaries. One group, comprising Boles, Beaughan, Carrick, and Jackson Creeks, rises on the northwestern slopes of Mount Shasta. The other group, consisting of Dale and Eddy Creeks, and Shasta River west of U. S. Highway 99, rises on the eastern slopes of the Trinity Mountains. All these streams join the main stem Shasta River above Dwinnell Reservoir near the town of Weed. As the Shasta River flows northward from Dwinnell Reservoir to its confluence with the Klamath River, north of Yreka, it is joined by three major tributaries. Parks Creek, rising on the eastern slopes of the Trinity Mountains, enters from the west near the town of Gazelle. Big Springs Creek, from Big Springs Lake, enters from the east about a mile below Parks Creek. Little Shasta River, rising on the western slopes of the mountainous area between Butte Valley and Shasta Valley, enters from the east near the town of Montague.

The place of use is in Shasta Valley which is approximately 30 miles long and 30 miles wide. The valley has numerous small, coneshaped, volcanic hillocks scattered throughout its central portion that produce the effect of dividing the area into a number of distinctively separate parts. Because of these formations only about 141,000 acres of the approximately 507,000 acres within the valley are irrigable. The valley floor elevation averages approximately 3,000 feet.

Maps of the major stream systems in the Shasta River service area are presented as Figures 15 through 15i, pages 111 through 120.

### Basis of Service

The Shasta River watermaster service area was created on March 1, 1933. The appropriative water rights on this stream system were determined by a statutory adjudication which resulted in Decree No. 7035, Siskiyou County Superior Court, dated December 29, 1932.

The decree describes the water rights of the entire stream system in alphabetical order of users. The rights supervised by the watermaster are broken down into eight separate schedules. These are: Shasta River above its confluence with Big Springs Creek, 43 priorities; Boles Creek, 20 priorities; Beaughan Creek, 5 priorities; Jackson Creek, 7 priorities; Carrick Creek, 13 priorities; Parks Creek, 25 priorities; Shasta River below its confluence with Big Springs Creek and Big Springs Creek and tributaries, 29 priorities; and Little Shasta River, 7 priorities. Additional schedules include Willow Creek, Yreka Creek, and miscellaneous independent springs, gulches, and sloughs, but these are not included in the service area.

Montague Water Conservation District has appropriative rights for storage of Shasta River and Parks Creek water in Dwinnell Reservoir (Lake Shastina). By agreement with the District, five nearby downstream users receive water from storage in lieu of their decreed continuous flow allotments. The watermaster handles the reservoir releases for these users as well as for the district itself.

A peculiarity of the Shasta River decree is that it defines only appropriative rights and excludes a number of riparian users on the lower Shasta River. Owners of these rights are not subject to watermaster supervision, causing considerable distribution problems during seasons of short water supply.

There are presently 110 water users in the service area with allotments totaling 602.322 cubic feet per second.

## Water Supply

The water supply for Shasta Valley is derived from snowmelt runoff, springs and underground flow, and occasional summer thundershowers. In several portions of the stream system the springs from underground flow are adequate to supply most allotments throughout the season. Much of the underground flow is derived from the northern slopes of Mount Shasta, which rises to an elevation of 14,162 feet at the south end of Shasta Valley. Although the snowpack on Mount Shasta is usually heavy, there is negligible surface runoff.

Parks Creek, Upper Shasta River, and Little Shasta River derive a major portion of their water supply from snowmelt runoff. This flow is usually adequate to supply all allotments until the middle of May.

Beaughan Creek, Carrick Creek, Shasta River from Boles Creek to Dwinnell Reservoir, Big Springs, and Lower Shasta River have enough runoff from springs to supply a large percentage of the allotments throughout the season.

Records of the daily mean discharge at several stream gaging stations in the Shasta River service area are presented in Tables 32, 33, 35, 36, 37 and 38; pages 107, 109, and 110. The daily mean storage in Dwinnell Reservoir is presented in Table 34, page 108.

#### Method of Distribution

Irrigation of permanent pasture and alfalfa lands is accomplished principally by wild flooding. Much of the return water is recaptured and used on lower pasture lands. Sprinkling systems are used for irrigating some alfalfa and grain lands.

Water is diverted primarily by diversion dams and then conveyed by ditch

or canal to the place of use. The largest and longest canal in the area is the Edson-Foulke Yreka Ditch, which has a capacity of about 60 cubic feet per second and a length of about 14 miles. Water is also supplied into ditch systems by pumped diversions, the three largest belonging to two irrigation districts and a private water users association. Some riparian lands are also served by pump diversions.

Many privately owned storage reservoirs exist in the area. Water storage from these reservoirs is used to supplement continuous-flow allotments.

Because of their large rights, close surveillance of two public agencies, Grenada and Big Springs Irrigation Districts, and the privately operated Shasta River Water Users Association, is very important, particularly in dry years. Control of releases from Montague Water Conservation District's Dwinnell Reservoir (Lake Shastina) is another responsibility of the watermaster. This includes measurement of deliveries of stored water to users just below the dam.

#### 1974 Distribution

John A. Nolan, Water Resources Technician II, was watermaster in the Shasta River service area from April 1 through September 30.

The available water supply in the service area was generally above average during the season.

Parks Creek. The flow in Parks Creek was sufficient to supply all allotments (25 priorities) until mid-July. Some water continued to be diverted into the Yreka Ditch until early September. The first priority allotments of 6 cfs were available throughout the entire irrigation season.

Water users downstream from the lowest first priority diversion received a portion of their allotments during the latter part of the season from return flow and from water rising in the gravel streambed. Upper Shasta River. During early spring, enough water was available to satisfy all allotments (eight priorities). As the flow decreased, the following levels of priority allotments were met: August 5 - all of fourth priority; August 19 - all of third priority (Yreka Ditch main allotment); and September 12 (the seasonable low) - 25 percent of third priority.

Shasta River from Boles Creek to Dwinnell Reservoir. Boles Creek and this
portion of the Shasta River were operated as one stream, under a longstanding oral agreement among the
water right owners. The water is distributed on a correlative, equal-priority
basis. Adequate water was available
to satisfy 100 percent of all allotments
throughout the entire season.

Beaughan Creek. The flow of Beaughan Creek was sufficient to satisfy most demands (five priorities) for the entire season. The creek is routed through a mill pond owned by the International Paper Company which uses approximately 35 percent of the flow for industrial purposes.

Carrick Creek. The water supply in Carrick Creek was adequate to satisfy all allotments (13 priorities) during the entire irrigation season.

Little Shasta River. Enough water was available in Little Shasta River to satisfy all fifth priority allotments (seven priorities) until mid-July, at which time full regulation became necessary to adequately distribute this priority. The flow continued to decrease to approximately 50 percent of the fourth priority allotments by late August. It then stayed constant for the remainder of the season.

The daily mean discharge of Little Shasta River near Montague is presented in Table 36, page 109. This runoff is augmented by rising water along the river channel, and by substantial inflow from Cleland Springs, a tributary approximately 2 miles below the stream gaging station. Therefore, considerably more water was available for distribution at downstream diversion points than is reported in the discharge table.

Dwinnell Reservoir. Releases from Dwinnell Reservoir to the Montague Water Conservation District, commenced on April 21 and continued into October. Reservoir operation data for the 1974 season are shown in Tables 34 and 35, pages 108 and 109.

By agreement with the Montague Water Conservation District, water users on Shasta River below Dwinnell Reservoir received stored water from the reservoir on demand in lieu of their natural flow rights. The agreement allotment totals and the amount delivered to each user this season are shown in the tabulation on the following page.

Big Springs. The flow of Big Springs was sufficient to satisfy approximately 50 percent of third priority allotments through the first half of the season. As usual during July, August, and September, the flow in Big Springs increased due to snowmelt from higher elevations on Mount Shasta, percolating into the ground and reappearing as surface flow at Big Springs Lake. As a result, the Big Springs Irrigation District, a third priority water right owner, was able to pump its full allotment from late July through the remainder of the season.

Lower Shasta River. The water supply in Lower Shasta River was sufficient to satisfy all allotments (29 priorities) during the entire season.

# South Fork Pit River Watermaster Service Area

The South Fork Pit River service area is located primarily in southeastern Modoc County, with a small portion extending into northeastern Lassen County. Figures 16 through 16d, pages 125 through 129, show the South Fork and its tributaries, with roads, etc.

The major source of water for this service area is the South Fork Pit River and its tributaries which rise on the western slopes of the Warner Mountains. The river flows in a westerly direction, entering South Fork Valley near Likely. It then flows north through the valley to its confluence with the North Fork Pit River just south of Alturas. The South Fork Pit River is joined from the east by Fitzhugh Creek near the middle of the valley and by Pine Creek near Alturas.

The major area of water use is in South Fork Valley between Likely and Alturas. South Fork Valley is about 16 miles long and 3 miles wide, with the valley floor lying at an elevation of about 4,500 feet. The valley is bounded on both sides by a rocky plateau that separates it from the surrounding mountains.

### Basis of Service

The Pine Creek agreement established water rights on Pine Creek November 22, 1933, and this stream system was added to the South Fork Pit River area on January 12, 1935. Pine Creek Reservoir, a small reservoir above all diversions, was originally used for power generation. This reservoir, now a recreation site, has a small water right but is not in the service area.

A large reservoir, West Valley Reservoir, was built in 1937 to increase the supply and extend the season for irrigation in the South Fork Irrigation District. The water rights for use from West Valley Reservoir total 23,100 acre-feet.

Pine Creek water rights were established by agreement on November 22, 1933, and watermaster service began January 12, 1935. Pine Creek Reservoir, a small reservoir above all diversions, was originally used for power generation. This reservoir, now a recreation site, has a small water right but is not in the service area.

The South Fork Pit River decree and the Pine Creek agreement establish two priorities on the respective systems. There are 36 owners of decreed water rights in the service area with total allotments of 350.97 cubic feet per second.

# Water Supply

The water supply for Pine Creek is derived mostly from snowmelt runoff. Therefore, runoff is usually small in the early spring, increases to a peak in May as temperatures rise, and then gradually decreases throughout the remainder of the season. Water users supplement their irrigation supplies from other sources whenever possible.

The water supply for Fitzhugh Creek consists of snowmelt runoff early in the season and supplemental water diverted from Mill Creek above Jess Valley later in the season. Surplus water from Fitzhugh Creek is diverted into the Payne and French Reservoirs through Payne-French Ditch (Diversion 136) until about June, when the diversion is adjusted to allow sufficient flow to supply downstream allotments. By July the creek has normally receded until only first priority allotments are available.

Payne Ditch (Diversion 1) is opened to import water from Mill Creek to Fitzhugh Creek when the snow has melted enough to allow access. This imported water is rediverted from North Fork Fitzhugh Creek through the Bowman Ditch to the Bowman Ranch. Return flow from

Bowman Ranch to the creek is rediverted through Diversion 136.

The water supply for the South Fork Pit River is derived primarily from snowmelt runoff, supplemented by water released from West Valley Reservoir. A number of streams, which rise at high elevations, collect at the mouth of Jess Valley to form the South Fork Pit River. West Valley Reservoir is located on West Valley Creek which enters the river below Jess Valley.

Most of the water users on the South Fork Pit River, except those in Jess Valley, are in the South Fork Irrigation District. The district stores water in West Valley Reservoir, which has a capacity of 23,000 acre-feet. and releases it to the South Fork Pit River as a supplemental supply when the natural flow becomes insufficient to meet demands. This usually occurs during the middle of June. Reservoir releases, together with the natural flow, are distributed by the watermaster in cooperation with the board of directors of the irrigation district. Except for extremely dry years, natural flow, combined with stored water, is sufficient to supply all demands for water on the South Fork Pit River throughout the irrigation season.

Records of the daily mean discharge of the several stream gaging stations in the area are presented in Tables 39 through 42, pages 123 and 124.

#### Method of Distribution

Trrigation of the lands along tributary streams is accomplished by flooding through use of small lateral ditches. The water is distributed on a continuous-flow basis to each user through gravity-flow diversion systems. In some cases, rotation is practiced among several users.

Most irrigation in the South Fork Pit River area is by the check and border method. The lands receive water essentially on demand by supplementing natural flow with releases from West Valley Reservoir. However, irrigation must be coordinated between the various ranches to eliminate large peak demands from the reservoir and to use the return flow as much as possible. Actual distribution varies each year as there is no specific irrigation schedule in use.

Distribution to the South Fork Pit River users is carried out on an equal and correlative basis in accordance with the water requirements for each ranch. This method of operation was made possible by construction of West Valley Reservoir in 1937.

### 1974 Distribution

Watermaster service began April 1 and continued until October 12. L. L. Bates, Water Resources Engineering Associate, was the watermaster for this season.

The water supply for the 1974 irrigation season was 73 percent of average.

Pine Creek. The flow remained low early in the season due to cold weather. There was sufficient water until haying ended, then very close regulation was required. From July until irrigation was finished, only 50 percent of priorities could be met.

Fitzhugh Creek. There was surplus water for all users until mid-June. The flow receded during the remainder of the season until only a portion of first priorities were served. Two new gaging stations were installed to study available winter surplus flows.

South Fork Pit River. West Valley Reservoir filled and spilled early in the season and all users enjoyed an abundance of water until the end of July. From August until the end of the season, the users above West Valley Reservoir received all of their first priorities and approximately 90 percent of second priorities. The users below West Valley received all waters needed from storage on a demand basis.

# Surprise Valley Watermaster Service Area

The Surprise Valley service area is situated in extreme eastern Modoc County, east of the Warner Mountains. Figure 17, page 141, shows the service area, the streams serving it, and the towns and roads of the valley.

Ten individual stream systems rising on the eastern slope of the Warner Mountains supply water to the area. These streams are fed by snowmelt runoff and traverse a fast, precipitous course down the eastern slope of the Warner Mountains to the valley floor where numerous scattered diversion ditches convey water to the irrigated lands.

### Basis of Service

The Surprise Valley watermaster service area was created January 10, 1939, including Mill, Soldier, Pine, Cedar, Deep, Owl, Rader, and Emerson Creeks, all of which previously had watermaster service individually. Service was started on Eagle Creek at that time. Bidwell Creek was added to the service area March 16, 1960. Each of the 10 stream systems are under separate decrees. There are 171 owners of decreed water rights in the service area with their rights totaling 313.75 cubic feet per second. See Table 43, page 132, for specific data regarding the decrees and water rights on the individual creeks.

### Water Supply

The water supply is derived almost entirely from snowmelt runoff, with only minor spring-fed flows occurring in the latter part of the season. Due to the steep eastern slope of the Warner Mountains, there are no known economically justified storage sites on the service area streams. Because of the lack of such regulatory storage, the available water supply at any specific diversion point may vary considerably within a few hours. An extreme diurnal temperature

variation causes extensive variation in snowmelt runoff. This problem is further aggravated by the relatively short, steep drainage area. In addition, occasional summer thundershowers may cause a creek to discharge a flow of mammoth proportions for several hours. These flashes are apt to cause considerable damage in the form of washouts and debris deposition and are of such short duration that no beneficial use can be made of the water.

Records of the daily mean discharge at several stream gaging stations within the service area are presented in Tables 44 through 54, pages 135 through 140.

#### Method of Distribution

The continuous-flow method of distribution is employed on most creeks; however, in a few instances the available water supply is rotated among the users in accordance with either decree schedules or by mutual agreement.

Alfalfa and meadow hay, the major crops grown in the valley, are irrigated in most instances by wild flooding, although some lands depend upon subsurface irrigation. Also, sprinkler irrigation with surface water is a recent trend. A few of these systems work by gravity, but most employ pumps with the surface water supplemented by deep wells. Many additional acres have been put into production during the past few years through the use of deep wells. Only surface water supplies are under state watermaster service.

To facilitate distribution of irrigation water, construction of permanent diversion dams, headgates, and measuring devices has been stressed during recent years. Although these structures do not solve the problems of discharge variation and debris deposition, they do provide significant assistance in solving water

TABLE 43
DECREES AND RELATED DATA - SURPRISE VALLEY STREAMS

C ree k	Mode No.	oc County St Court Decre Date		Service Area Created	No. of Water Right Owners	Total Cubic Feet Per Second	Remarks

d/ See remarks.

measurement and distribution problems. The individual streams and locations of the diversions are shown on Figures 17 through 17j, pages 141 through 152.

Although the Owl Creek Flood Control and Water Conservation District did not become official until August 7, 1961, the district's diversion and distribution project was completed in February, 1961. The project reduced the number of diversions from 17 to 2 and the number of ditches from 17 to 8. This makes distribution easier and more equitable. The users say that they receive twice as much water as they did before the project. It is possible to divert and distribute 80 cubic feet per second in the lower seven ditches.

### 1974 Distribution

Watermaster service began in the Surprise Valley service area on March 19 and continued until September 30. Charles H. Holmes, Assistant Engineer, Water Resources, was watermaster during this period.

Streams in the northern half of the valley had approximately normal runoff, while streamflow in the southern half was above normal. Very good crop yields were experienced throughout the valley, especially by ranchers who supplemented their irrigation by ground water pumping.

Ridwell Creek. Total stream runoff available to Bidwell Creek users during the period April 1 through September 30 was 15,317 acre-feet, or approximately 142 percent of normal. July 1 streamflow was adequate to supply 49 percent of first priority allotments on Schedule 3. When Schedule 4 became effective July 10, streamflow was adequate to supply the first, second, and 33 percent of third priorities. Streamflow gradually diminished until September 18 at which time 16 percent of second priority was available. streamflow remained constant at this flow until September 30, the end of the watermaster season.

Mill Creek. Total stream runoff available to Mill Creek users during the period April 1 to September 30 was 4,368 acre-feet or approximately 86 percent of normal.

Fourth priority water rights were filled from May 7 until June 6, after which the flow diminished until August 5 when the full second priority was available. At the end of September 95 percent of the first priority rights were being served.

Soldier Creek. Total stream runoff available to Soldier Creek users from March 19 through September 30 was 3,435 acre feet or approximately 93 percent of normal.

The flow was adequate to supply both upper and lower users at full eighth priority from April 30 to May 28. The flow receded from that time until June 19 when 92 percent of the second priority rights were being satisfied. When the "season outside of the general irrigation season" started June 19, the flow was adequate to supply only 45 percent of the fourth priority. From August 1 to September 30 only partial first priority rights were served.

Pine Creek. Total stream runoff available to Pine Creek users during the period March 20 to September 30 was 1,749 acre-feet, or approximately 125 percent of normal.

There was sufficient water for each of the water users to receive four irrigations on rotation by May 19. From that time until June 22 the flow was diverted to the Cal-Vada Ranch. On June 22 the flow was turned into the Cressler Ditch where it continued until August 1 at which time the water failed to reach the place of use. Pine Creek was dry from August 6 until the end of the season.

Cedar Creek. Total stream runoff available to Cedar Creek users during the period April 1 through September 30 was 3,031 acre-feet, or approximately 116 percent of normal. Early streamflow

was adequate to supply demands. However, by May 18 only first priority and 50 percent of the second priority could be satisfied. Warrens and Wiley supplemented their allotment with water imported from Thoms Creek. From June 14 through the remainder of the season only a portion of the first priority could be satisfied, with only 4 percent by September 30.

Deep Creek. Total stream runoff available to Deep Creek users from April 1 to September 30 was 3,478 acre-feet, or approximately 95 percent of normal.

The flow in North Deep creek was adequate to supply all the decreed rights until May 14. (North Deep Creek has only one priority and one diversion.) From May 14 on, the flow receded steadily until September 30 when only 8 percent of the priority was available.

During the month of April the flow in South Deep Creek fluctuated from 28 percent of the second priority to 60 percent of the third priority. All five priorities were filled for only 3 days (May 8 to May 10), after which the flow diminished. By June 10 only the first priority was satisfied. South Deep Creek continued to recede until September 30 when only 11 percent of the first priority was available.

Owl Creek. The total stream runoff available to Owl Creek users from April 1 to September 30 was 7,736 acrefeet, or approximately 117 percent of normal.

The streamflow during the month of April fluctuated from satisfying the tenth to fourteenth priorities with

the average at the eleventh priority. On May 8 all 21 priorities were met, but due to cooler weather the flow dropped below the fourteenth priority on May 14, then began climbing again. On May 25 the flow met and exceeded the twenty-first priority, remaining above it until June 24. It then gradually receded until September 30 when the flow was down to the fourth priority.

Rader Creek. The total stream runoff available to Rader Creek users from April 1 to September 30 was 4,944 acrefeet, or approximately 136 percent of normal.

Streamflow served the third priority from April 1 to May 4, increased to serve the full seventh priority from May 7 to May 12, receded to the third priority on May 22, increased to serve the full seventh priority from May 26 to June 30, diminished rapidly to the third priority on July 3 and then receded gradually to about 60 percent of the first priority on September 30.

Eagle Creek. Eagle Creek supplied all four priorities to about June 1. By early July only first and second priority water was available. Flows receded by mid-September to first priority water which was available for the remainder of the season.

Emerson Creek. Total stream runoff available to Emerson Creek users from April 1 to September 30 was 5,111 acre-feet, or approximately 140 percent.

Streamflow was adequate from April 1 to June 12 to satisfy the fourth priority, after which the flow receded gradually. On September 30 approximately 12 percent of the second priority was served.

### Susan River Watermaster Service Area

The Susan River service area is situated in southern Lassen County in the vicinity of Susanville. The primary area of water use is in Honey Lake Valley between Susanville and the northwest shore of Honey Lake, a distance of about 25 miles. The valley floor is at an elevation of about 4,000 feet. The source of supply is comprised of three stream systems: the Susan River, Baxter Creek, and Parker Creek, with their respective tributaries.

The Susan River originates on the east slope of the Sierra Nevada immediately east of Lassen National Park at an elevation of about 7,900 feet. Its channel runs easterly from Silver Lake through McCoy Flat Reservoir, the town of Susanville, and then to Honey Lake.

The Susan River has four major tributaries: Piute Creek, entering from the north at Susanville; Gold Run and Lassen Creeks, entering from the south between Susanville and Johnstonville; and Willow Creek, entering from the north above Standish. Gold Run and Lassen Creeks rise on the north slope of Diamond Mountain at an elevation of about 7,600 feet. The watersheds of Piute and Willow Creeks are on the south slopes of Round Valley Mountain at lower elevations.

A short distance below its confluence with Willow Creek, the Susan River divides into three channels: Tanner Slough Channel'on the north, Old Channel in the middle, and Dill Slough Channel on the south. Hartson Slough and Whitehead Slough divert from Dill Slough on its south bank farther downstream.

The Baxter Creek stream system is in Honey Lake Valley on the east slope of the Sierra Nevada, about 10 miles southeast of Susanville. The principal creeks in the system are: Baxter Creek, which rises in the extreme western

portion of the basin and flows in an easterly direction, and Elesian, Sloss, and Bankhead Creeks, tributaries of Baxter Creek from the south.

Parker Creek is also in Honey Lake Valley on the east slope of the Sierra Nevada, about 15 miles southeast of Susanville. It rises on the east slope of Diamond Mountain and flows in an easterly direction for about 5 miles into Honey Lake.

Maps of the Susan River service area, showing the stream systems, diversions, etc., are presented as Figures 18 through 18f, pages 160 through 167.

### Basis of Service

The waters of Susan River and its tributaries are distributed in accordance with the water rights defined in Decree No. 4573, Lassen County Superior Court, entered on April 18, 1940. Schedule 3 of the decree defines the rights to the use of water from Willow Creek in Willow Creek Valley, Lower Willow Creek, and the Susan River delta below the Colony Schedule 4 of the decree defines the rights to the use of water from Gold Run, Piute, Hills, Holtzclaw, and Lassen Creeks above their confluence with the Susan River. Schedules 5 and 6 of the decree define the rights to the use of water from the Susan River exclusive of its tributaries. The decree establishes three priority classes each on Susan River and Gold Run Creek, two on Willow Creek, and one each on Piute and Hills Creeks.

The water of Baxter Creek and its tributaries is distributed in accordance with the water rights defined in the statutory adjudication as set forth in Decree No. 8174, Lassen County Superior Court, dated December 15, 1955. Schedule 3 of the decree defines the rights to the use of water from Sloss and Bankhead Creeks and

Schedule 4 the rights to the use of water from Baxter and Elesian Creeks. The Baxter Creek rights are divided into five priority classes.

The water of Parker Creek and its tributaries is distributed in accordance with the water rights defined by a statutory adjudication as set forth in Decree No. 8175, Lassen County Superior Court, dated December 15, 1955. Schedule 3 of the decree defines the rights to the use of water from Parker Creek, with four priority classes.

The Susan River watermaster service area was created by order of the Division of Water Resources on November 10, 1941. The Baxter and Parker Creek stream systems were added to the Susan River service area on February 16, 1956. There are 160 water right owners in the service area with total allotments of 351.732 cubic feet per second.

#### Water Supply

The water supply in the Susan River service area is obtained from two major sources, snowmelt runoff and springs. Snowpack on the Willow Creek Valley and Piute Creek watersheds, which embrace more than one-half of the Susan River stream system, melts early in the spring and is usually depleted by May 1. Irrigation requirements from this portion of the stream system are then almost entirely dependent on the flow of springs that are relatively constant throughout the year.

Under average flow conditions, Lassen, Gold Run, Baxter, and Parker Creeks and the Susan River above Susanville are sustained by snowmelt runoff until early June. The flow from perennial springs in this portion of the system is comparatively small.

The Lassen Irrigation Company stores supplemental water in Hog Flat and McCoy Flat Reservoirs, on the headwaters of the Susan River. This stored water is released into the Susan River Channel and commingled with the natural flow, usually during June and July. It is then rediverted into Lake Leavitt for further distribution by the irrigation Company.

Records of daily mean discharge of the several stream gaging stations in the service area are presented in Tables 55 through 59, pages 157 through 159.

### Method of Distribution

Irrigation in the Susan River service area is accomplished by placing dams in the main channels, thus raising the water level for subsequent diversion into canals and ditches. These diversion dams are relatively large on the Susan River Channel and generally much smaller on the various creeks. Wild flooding is the most common method of irrigation in practice. Portions of the irrigated lands have been leveled, permitting a more efficient use of water by using border checks and furrows. Subirrigation occurs in some areas incidental to surface irrigation or as a result of seepage from ditches and creek channels.

The Lassen Irrigation Company is allowed to use its three reservoirs, McCoy Flat, Hog Flat and Lake Leavitt, to store water as follows: (a) between March 1 and July 1 when the flow in the river just above its confluence with Willow Creek is more than 20 cubic feet per second, and (b) at all other times when the flow at the same point is 5 cubic feet per second, in spite of the allotments outlined in Schedules 3, 6, and users of third priority class in Schedule 5 of the Susan River decree.

### 1974 Distribution

Watermaster service began in the Susan River service area on April 1 and continued until September 30 with Lester L. Lighthall, Water Resources Technician II, as watermaster.

The available natural water supply throughout the service area was

above average. An unusually heavy snow\_fall during March brought the snow survey measurements to above normal for the Susan River watershed. Many ranchers in the Honey Lake area reported record hay crops.

Parker Creek. The available water supply in Parker Creek was sufficient to satisfy all allotments (four priorities) until June 3. From June 3 to July 16 the flow decreased to first priority allotments. From July 16 throughout the remainder of the season only first priority allotments were served.

Baxter Creek. The available water supply in Baxter Creek was sufficient to supply all allotments (five priorities) until June 10. The flow rapidly decreased from June 10 to July 12 when approximately 60 percent of second priority allotments were supplied. The flow at Diversion 75 dropped to 1 cfs on July 25. From July 25 for the remainder of the season only stockwater allotments were served.

Lassen-Holtzclaw Creeks. The available water supply in Lassen-Holtzclaw Creeks was sufficient to meet all allotments (two priorities) until June 25. The flow decreased to first priority allotments on July 23. From July 23 throughout the remainder of the season the Tangeman Ranch was entitled to all of the water available in the stream.

Hills Creek. The available water supply in Hills Creek was sufficient to supply all allotments (one priority) until June 27, and all storage facilities on Hills Creek were filled by this date. First priority water declined until August 10 when only stockwater was available.

Gold Run Creek. The available water supply in Gold Run Creek was sufficient to supply allotments (three priorities) until June 25. Between June 25 and August 20, the flow decreased steadily. After August 20, the flow remained reasonably constant at about 15 percent of second priority allotments.

Piute Creek. The available water supply in Piute Creek was sufficient to satisfy all allotments (one priority) and provide a small surplus flow to the Susan River throughout the season.

Willow Creek. The available water supply in Willow Creek was sufficient to supply all allotments (two priorities) throughout the season.

Susan River. The available water supply in the Susan River was sufficient to supply all allotments in Schedule 6 (three priorities) until June 22. As the flow receded, Schedule 6 was terminated for the season. All allotments in Schedule 3 (three priorities - Lower Susan River) were satisfied until August 6. Throughout the remainder of the season there was enough water for about 60 percent of second priority allotments in this schedule.

All allotments in Schedule 5 (three priorities - Upper Susan River area) were satisfied until July 10. The flow receded until August 1 when there was enough water for about 15 percent of the second priority allotments. Throughout the remainder of the season the flow remained constant.

Lassen Irrigation Company Reservoirs.

The Susan River decree allows the Lassen Irrigation Company's McCoy Flat and Lake Leavitt Reservoirs to store surplus water during the winter and spring months. Once filled, or if a shortage occurs among downstream water right owners, the natural flow in the Susan River above McCoy Flat Reservoir must be released.

During spring runoff these two reservoirs' filled to capacity. Shortages began to occur in mid-June and the company requested that its releases to Lake Leavitt from Hog Flat Reservoir begin. Controlled releases began on June 19 and continued until August 12, at which time Hog Flat Reservoir was emptied. Releases from McCoy Flat Reservoir began on July 16 and continued until September 6.

## Special Occurrences

The Susan River recorder station at Johnstonville Bridge was relocated downstream approximately 1 mile at Diversion 44 dam.

The Susan River was Cleaned with a dragline to assure proper distribution of water at Tanner and Dill Sloughs.

### Willow Creek Watermaster Service Area

The Willow Creek service area is situated in Siskiyou County, about 10 miles northeast of Montague. A map showing the Willow Creek stream system, the diversions, and the principal roads in the area is presented in Figure 19, page 171. Willow Creek is the major source of water supply and rises on the west slope of 7,800-foot Willow Creek Mountain east of the service area. It then flows in a northwesterly direction through about 11 miles of rolling hills to its confluence with the Klamath River. The service area is about 8 miles long by 1 mile wide and varies in elevation between about 2,600 and 4,000 feet.

#### Basis of Service

Willow Creek has had a long history of litigation. However, the present basis of service might be said to have been initiated in 1949 when a civil suit was referred to the Department of Public Works, Division of Water Resources, to act as referee. The matter was never finalized by a decree. The issues involved were reopened in 1971, and by Decree No. 24482, dated April 28, 1972, the Siskiyou County Superior Court appointed the Department of Water Resources to supervise distribution of water in accordance with an earlier agreement between the users defining their respective rights. Accordingly, the Willow Creek watermaster service area was created on June 22, 1972, and service began on July 1, 1972.

There are three water users in the service area. Distribution is on a fractional basis until the flow drops to a specified amount below the upper two users. At that time, the total flow is rotated between the upper two users.

### Water Supply

The main source of water supply of the Willow Creek stream system is from the

melting of snow which accumulates at high elevations on the drainage area during the winter months. The spring flow from the melting snow begins late in March or early April and is almost entirely gone prior to June 1. Thereafter the flow decreases rapidly until about July 1. From that date up to the time fall rains begin, the flow remains at a more or less sustained low-flow stage sufficient for domestic and stockwatering purposes on the two upper ranches only.

### Method of Distribution

Both sprinkler and flood irrigation are used in the Willow Creek service area. The upper water user has the option of using gravity diversions for either flood or sprinkler irrigation. The middle user relies entirely on flood irrigation by both of these users. Diversion is accomplished by diverting water into the ditches by temporary rock or gravel dams. The lower user in the area utlizes both flood and sprinkler irrigation during the early season when the supply is abundant. As the supply dwindles, the remaining water is pumped from a sump to the sprinkler system.

#### 1974 Distribution

Watermaster service in the Willow Creek service area began on July 1 and continued until September 30. John A. Nolan, Water Resources Technician II, was watermaster during this period.

Since watermaster service began in 1972 on this creek, there are no records for a basis of comparison of this year's water supply with an average. However, the water users indicated that the supply was far above average.

On July 1 there was still sufficient water to distribute to all three users according to their fractional allotments. On July 20 distribution was started on a

5-day rotation between the two upper users since the lower user's allotment was no longer reaching its place of use. This rotation was continued for the remainder of the season.
